PROPERLY DISCONTINUOUS ACTIONS, GROWTH INDICATORS, AND CONFORMAL MEASURES FOR TRANSVERSE SUBGROUPS

DONGRYUL M. KIM, HEE OH, AND YAHUI WANG

Abstract. Let $G$ be a connected semisimple real algebraic group. The class of transverse subgroups of $G$ includes all discrete subgroups of rank one Lie groups and any subgroups of Anosov or relative Anosov subgroups. Given a transverse subgroup $\Gamma$, we show that the $\Gamma$-action on the Weyl chamber flow space determined by its limit set is properly discontinuous. This allows us to consider the quotient space and define Bowen-Margulis-Sullivan measures. We then establish the ergodic dichotomy for the Weyl chamber flow, in the original spirit of Hopf-Tsuji-Sullivan. We also introduce the notion of growth indicators and discuss their properties and roles in the study of conformal measures, extending the work of Quint. We discuss several applications as well.

1. Introduction

Patterson-Sullivan theory on conformal measures of a discrete subgroup of a rank one simple real algebraic group $G$ has played a pivotal role in the study of dynamics on rank one homogeneous spaces. One of the basic results

Oh is partially supported by the NSF grant No. DMS-1900101.
due to Sullivan in 1979 is the relation between the support of a conformal measure and its dimension, which we recall for $G = \text{SO}^\circ(n, 1)$, the identity component of the special orthogonal group $\text{SO}(n, 1)$. The group $\text{SO}^\circ(n, 1)$ is the group of orientation-preserving isometries of the real hyperbolic space $(\mathbb{H}^n, d)$. The geometric boundary of $\mathbb{H}^n$ can be identified with the sphere $S^{n-1}$. For a discrete subgroup $\Gamma < G$, denote by $\Lambda^\text{con} \subset S^{n-1}$ the conical set of $\Gamma$, which consists of the endpoints of all geodesic rays in $\mathbb{H}^n$ which accumulate modulo $\Gamma$. Let $\delta_\Gamma$ denote the critical exponent of $\Gamma$, which is the abscissa of convergence of the Poincaré series $s \mapsto \sum_{\gamma \in \Gamma} e^{-s d(o, \gamma o)}$, $o \in \mathbb{H}^n$.

For a given $\Gamma$-conformal measure $\nu$, we denote by $m_\nu$ the Bowen-Margulis-Sullivan measure on the unit tangent bundle $T^1(\Gamma \setminus \mathbb{H}^n)$, which is a locally finite measure invariant under the geodesic flow. The following theorem is often referred to as the Hopf-Tsuji-Sullivan dichotomy (see [41], [17], [40], [1], [37, Theorem 1.7]).

**Theorem 1.1** (Sullivan, [40, Corollaries 4, 20, Theorem 21], see also [1], [10], [37]). Let $\Gamma < \text{SO}^\circ(n, 1)$, $n \geq 2$, be a non-elementary discrete subgroup. Suppose that there exists a $\Gamma$-conformal measure $\nu$ on $S^{n-1}$ of dimension $s \geq 0$.

1. We have
   \[ s \geq \delta_\Gamma. \]

2. The following are equivalent:
   \begin{enumerate}
     \item $\sum_{\gamma \in \Gamma} e^{-s d(o, \gamma o)} = \infty$ (resp. $\sum_{\gamma \in \Gamma} e^{-s d(o, \gamma o)} < \infty$);
     \item $\nu(\Lambda^\text{con}) = 1$ (resp. $\nu(\Lambda^\text{con}) = 0$);
     \item the geodesic flow on $(T^1(\Gamma \setminus \mathbb{H}^n), m_\nu)$ is completely conservative and ergodic.
   \end{enumerate}

   (resp. the geodesic flow on $(T^1(\Gamma \setminus \mathbb{H}^n), m_\nu)$ is completely dissipative and non-ergodic.)

   In the former case, $s = \delta_\Gamma$ and $\nu$ is the unique $\Gamma$-conformal measure of dimension $\delta_\Gamma$.

The main aim of this paper is to establish an analogous result for a class of discrete subgroups of a general connected semisimple real algebraic group $G$, called $\theta$-transverse subgroups. The class of $\theta$-transverse subgroups includes all discrete subgroups of rank one Lie groups, $\theta$-Anosov subgroups and their relative versions. This class is regarded as a generalization of all rank one discrete subgroups while Anosov subgroups are regarded as higher rank analogues of convex cocompact subgroups.

We need to introduce some notations to state our results precisely. Let $P < G$ be a minimal parabolic subgroup with a fixed Langlands decomposition $P = MAN$ where $A$ is a maximal real split torus of $G$, $M$ is the maximal compact subgroup of $P$ commuting with $A$ and $N$ is the unipotent radical of $P$. Let $\mathfrak{g}$ and $\mathfrak{a}$ respectively denote the Lie algebra of $G$ and $A$. Fix a positive Weyl chamber $\mathfrak{a}^+ < \mathfrak{a}$ so that $\log N$ consists of positive root subspaces and set $A^+ = \exp \mathfrak{a}^+$. We fix a maximal compact subgroup $K < G$ such that the
Cartan decomposition $G = KA^+K$ holds. We denote by $\mu : G \to a^+$ the Cartan projection defined by the condition $g \in K \exp \mu(g)K$ for $g \in G$. Let $\Pi$ denote the set of all simple roots for $(g, a^+)$. As usual, the Weyl group is the quotient of the normalizer of $A$ in $K$ by the centralizer of $A$ in $K$. Let $i : a \to a$ denote the opposition involution, that is, $i(u) = -Ad_{w_0}(u)$ for all $u \in a$ where $w_0$ is the longest Weyl element. It induces an involution on $\Pi$ which we denote by the same notation $i$. Throughout the introduction, we fix a non-empty subset $\theta \subset \Pi$.

Let $\theta = \bigcap_{\alpha \in \Pi - \theta} \ker \alpha$ and let $p_{\theta} : a \to a_{\theta}$ be the unique projection, invariant under all Weyl elements fixing $a_{\theta}$ pointwise. Let $P_{\theta}$ be the standard parabolic subgroup corresponding to $\theta$ (our convention is that $P = P_{\Pi}$) and consider the $\theta$-boundary:

$F_{\theta} = G/P_{\theta}$.

We say that $\xi \in F_{\theta}$ and $\eta \in F_{i(\theta)}$ are in general position if the pair $(\xi, \eta)$ belongs to the unique open $G$-orbit in $F_{\theta} \times F_{i(\theta)}$ under the diagonal action of $G$.

Let $\Gamma < G$ be a Zariski dense discrete subgroup. The following properties of $\Gamma$ are natural to consider in studying analogues of Theorem 1.1 for $\Gamma$-conformal measures on the $\theta$-boundary $F_{\theta}$. Let $\Lambda_{\theta} = \Lambda_{\theta}(\Gamma)$ denote the $\theta$-limit set of $\Gamma$, which is the unique $\Gamma$-minimal subset of $F_{\theta}$ (Definition 5.1).

**Definition 1.2.** A discrete subgroup $\Gamma$ is said to be $\theta$-transverse if

- $\Gamma$ is $\theta$-regular, i.e., $\lim \inf_{\gamma \in \Gamma} \alpha(\mu(\gamma)) = \infty$ for all $\alpha \in \theta$; and
- $\Gamma$ is $\theta$-antipodal, i.e., if any two distinct $\xi, \eta \in \Lambda_{\theta,i(\theta)}$ are in general position.

Note that the $\theta$-transverse property is hereditary: a subgroup of a $\theta$-transverse subgroup is also $\theta$-transverse.

We assume that $\Gamma$ is $\theta$-transverse in the rest of the introduction. We define the $\theta$-growth indicator $\psi^\theta_T : a_{\theta} \to [-\infty, \infty]$ as follows: fixing any norm $\| \cdot \|$ on $a_{\theta}$, if $u \in a_{\theta}$ is non-zero,

$$\psi^\theta_T(u) = \|u\| \inf_{u \in C} \tau^\theta_C$$

where $\tau^\theta_C$ is the abscissa of convergence of the series $\sum_{\gamma \in \Gamma, \mu(\gamma) \in C} e^{-s\|\mu(\gamma)\|}$ and $C \subset a_{\theta}$ ranges over all open cones containing $u$. Set $\psi^\theta_T(0) = 0$. This definition is independent of the choice of a norm on $a_{\theta}$. For $\theta = \Pi$, $\psi^\Pi_T$ coincides with Quint's growth indicator $\psi_T$ [33]. For a general $\theta \subset \Pi$, we have:

$$\psi^\theta_T \circ p_{\theta} \geq \psi_T$$

(Lemma 3.12, see also Lemma 3.13 for a precise relation for $G$ simple). We show that $\psi^\theta_T < \infty$, and $\psi^\theta_T$ is a homogeneous, upper semi-continuous and concave function. It also follows from (1.2) that

$$\{\psi^\theta_T \geq 0\} = L_{\theta} \quad \text{and} \quad \psi^\theta_T > 0 \quad \text{on int } L_{\theta}$$

(1.3)
where $\mathcal{L}_\theta = \mathcal{L}_\theta(\Gamma)$ is the $\theta$-limit cone of $\Gamma$ (Theorem 3.3).

Denote by $a^*_\theta = \text{Hom}(a_\theta, \mathbb{R})$ the space of all linear forms on $a_\theta$. For $\psi \in a^*_\theta$, a Borel probability measure $\nu$ on $\mathcal{F}_\theta$ is called a $(\Gamma, \psi)$-conformal measure if

$$\frac{d\gamma_*\nu}{d\nu}(\xi) = e^{\psi(\beta_\xi(\nu, \gamma))} \quad \text{for all } \gamma \in \Gamma \text{ and } \xi \in \mathcal{F}_\theta$$

where $\gamma_*\nu(D) = \nu(\gamma^{-1}D)$ for any Borel subset $D \subset \mathcal{F}_\theta$ and $\beta_\xi$ denotes the $a_\theta$-valued Busemann map defined in (5.4). We find it convenient to call the linear form $\psi$ the dimension of $\nu$.

We define the $\theta$-conical set of $\Gamma$ as

$$\Lambda^\con_{\theta} = \{ gP_\theta \in \mathcal{F}_\theta : \limsup_{\Gamma} gM_\theta A^+ \neq \emptyset \}, \quad (1.4)$$

where $M_\theta = K \cap P_\theta$ (see Lemma 5.4 for an equivalent definition). If $\Gamma$ is $\theta$-regular, then $\Lambda^\con_{\theta} \subset \Lambda_{\theta}$ (Proposition 5.6).

**Definition 1.3.** We say $\psi \in a^*_\theta$ is $(\Gamma, \theta)$-proper if $\psi \circ \mu_\theta : \Gamma \to [-\epsilon, \infty)$ is a proper map for some $\epsilon > 0$.

For example, a linear form $\psi \in a^*_\theta$ which is positive on $\mathcal{L}_\theta - \{0\}$ is $(\Gamma, \theta)$-proper. For a $(\Gamma, \theta)$-proper form $\psi$, the critical exponent $0 < \delta_\psi = \delta_\psi(\Gamma) \leq \infty$ of the $\psi$-Poincaré series $P_\psi(s) = \sum_{\gamma \in \Gamma} e^{-s\psi(\mu_\theta(\gamma))}$ is well-defined and we have

$$\delta_\psi = \limsup_{t \to \infty} \frac{1}{t} \# \{ \gamma \in \Gamma : \psi(\mu_\theta(\gamma)) < t \}$$

(see Lemma 4.2).

A linear form $\psi \in a^*_\theta$ is said to be $(\Gamma, \theta)$-critical if $\psi$ is tangent to the $\theta$-growth indicator $\psi^\theta_{\Gamma}$, i.e., $\psi \geq \psi^\theta_{\Gamma}$ and $\psi(u) = \psi^\theta_{\Gamma}(u)$ for some $u \in a^+_\theta - \{0\}$.

**Main theorems.** Our main theorems extend Theorem 1.1 to higher rank.

**Theorem 1.4.** Let $\Gamma < G$ be a $\theta$-transverse subgroup. Suppose that there exists a $(\Gamma, \psi)$-conformal measure $\nu$ on $\mathcal{F}_\theta$ for $\psi \in a^*_\theta$.

1. If $\psi$ is $(\Gamma, \theta)$-proper, then

$$\psi \geq \psi^\theta_{\Gamma}. \quad (1.5)$$

2. The following are equivalent:

   a. $\sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} = \infty$ (resp. $\sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} < \infty$);

   b. $\nu(\Lambda^\con_{\theta}) = 1$ (resp. $\nu(\Lambda^\con_{\theta}) = 0$).

In the former case, any $(\Gamma, \theta)$-proper $\psi$ is necessarily $(\Gamma, \theta)$-critical and $\nu$ is the unique $(\Gamma, \psi)$-conformal measure on $\mathcal{F}_\theta$.

For $\theta = \Pi$, Theorem 1.4.1 was proved by Quint and for a general $\theta$, only a weaker bound as (8.7) was known [34, Theorem 8.1]. It implies:

**Theorem 1.5.** Let $\Gamma < G$ be a $\theta$-transverse subgroup. If there exists a $(\Gamma, \psi)$-conformal measure on $\mathcal{F}_\theta$ for a $(\Gamma, \theta)$-proper $\psi \in a^*_\theta$, then

$$\delta_\psi \leq 1.$$
Remark 1.6. (1) Canary-Zhang-Zimmer [9] proved the equivalence of (a) and (b) in Theorem 1.4(2) for θ symmetric, that is, θ = i(θ), and for conformal measures supported on Λθ. We mention that transverse subgroups are sometimes called RA-subgroups (cf. [12]).

(2) For some special class of θ-Anosov subgroups and for conformal measures supported on Λθ, Theorem 1.5 was also proved in [32, Theorem C]. Although [32, Theorem C] is claimed for general conformal measures on Fθ, its proof works only for measures supported on Λθ.

As in the original Hopf-Tsuji-Sullivan dichotomy (Theorem 1.1), Theorem 1.4 can be extended to the dichotomy on the ergodicity of the Weyl chamber flow. Recalling the Hopf parametrization \( \Gamma \setminus (F_\theta(2) \times a) \simeq \Gamma \backslash G/M \), a natural space to consider is the quotient space \( \Gamma \setminus (F_\theta(2) \times a_\theta) \) where \( F_\theta(2) = \{ (\xi, \eta) \in F_\theta \times F_i(\theta) : \xi, \eta \text{ are in general position} \} \) and \( \Gamma \) acts on \( F_\theta(2) \times a_\theta \) from the left by

\[
\gamma.(\xi, \eta, u) = (\gamma \xi, \gamma \eta, u + \beta_\xi(\gamma^{-1}, e))
\]

for all \( \gamma \in \Gamma \) and \( (\xi, \eta, u) \in F_\theta(2) \times a_\theta \). However the \( \Gamma \)-action on \( F_\theta(2) \times a_\theta \) is not properly discontinuous in general; so the quotient space \( \Gamma \setminus (F_\theta(2) \times a_\theta) \) is not locally compact.

On the other hand, the restriction of the \( \Gamma \)-action on the subspace \( \Lambda_\theta(2) \times a_\theta \) turns out to be properly discontinuous where \( \Lambda_\theta(2) = F_\theta(2) \cap (\Lambda_\theta \times \Lambda_i(\theta)) \) (Theorem 9.1):

**Theorem 1.7** (Properly discontinuous action). Let \( \Gamma < G \) be a \( \theta \)-transverse subgroup. Then the \( \Gamma \)-action on \( \Lambda_\theta(2) \times a_\theta \) given by (1.6) is properly discontinuous, and hence the quotient space

\[
\Omega_\theta := \Gamma \setminus \Lambda_\theta(2) \times a_\theta
\]

is a locally compact Hausdorff space on which \( a_\theta \) acts by translations from the right.

Remark 1.8. Indeed, more strong property of the action will be proved: for \( (\Gamma, \theta) \)-proper \( \varphi \in a_\theta^* \), we have a projection \( \Lambda_\theta(2) \times a_\theta \to \Lambda_\theta(2) \times \mathbb{R} \) given by \( (\xi, \eta, u) \mapsto (\xi, \eta, \varphi(u)) \). The action (1.6) descends to the action

\[
\gamma.(\xi, \eta, s) = (\gamma \xi, \gamma \eta, s + \varphi(\beta_\xi(\gamma^{-1}, e)))
\]

for all \( \gamma \in \Gamma \) and \( (\xi, \eta, s) \in \Lambda_\theta(2) \times \mathbb{R} \). We show that the action (1.7) is properly discontinuous and hence

\[
\Omega_\varphi := \Gamma \setminus \Lambda_\theta(2) \times \mathbb{R}
\]

is a locally compact Hausdorff space on which \( \mathbb{R} \) acts by translation from the right (Theorem 9.2). Moreover, we have a trivial \( \ker \varphi \)-bundle \( \Omega_\theta \to \Omega_\varphi \) so that \( \Omega_\theta \) is homeomorphic to \( \Omega_\varphi \times \ker \varphi \) (9.14).
For \( \psi \in a^*_\theta \), we denote by \( \mathcal{M}_\psi^\theta \) the space of all \((\Gamma, \psi)\)-conformal measures supported on \( \Lambda_\theta \). For a pair \((\nu, \nu_i) \in \mathcal{M}_\psi^\theta \times \mathcal{M}_{\psi \circ i}^{i(\theta)}\), we denote by \( m_{\nu, \nu_i} \) the associated Bowen-Margulis-Sullivan measure on \( \Omega_\theta \) (see (9.11) for its definition).

We expand Theorem 1.4 to the dichotomy on conservativity and ergodicity of the \( a_\theta \)-action on the space \((\Omega_\theta, m_{\nu, \nu_i})\). See Theorem 10.2 for a more elaborate statement.

**Theorem 1.9.** Let \( \Gamma < G \) be a \( \theta \)-transverse subgroup. Let \( \psi \in a^*_\theta \) be \((\Gamma, \theta)\)-proper such that \( \mathcal{M}_\psi^\theta \neq \emptyset \). In each of the following complementary cases, the claims (1) – (4) are equivalent to each other.

The first case:

1. \( \sum_{\gamma \in \Gamma} e^{-\psi(\mu_\psi(\gamma))} = \infty \);
2. For any \( \nu \in \mathcal{M}_\psi^\theta \), \( \nu(\Lambda_\theta^{\text{con}}) = 1 \);
3. For any \((\nu, \nu_i) \in \mathcal{M}_\psi^\theta \times \mathcal{M}_{\psi \circ i}^{i(\theta)}\), the \( \Gamma \)-action on \((\Lambda_\theta^{(2)}, \nu \times \nu_i)\) is completely conservative and ergodic;
4. For any \((\nu, \nu_i) \in \mathcal{M}_\psi^\theta \times \mathcal{M}_{\psi \circ i}^{i(\theta)}\), the \( a_\theta \)-action on \((\Omega_\theta, m_{\nu, \nu_i})\) is completely conservative and ergodic.

The second case:

1. \( \sum_{\gamma \in \Gamma} e^{-\psi(\mu_\psi(\gamma))} < \infty \);
2. For any \( \nu \in \mathcal{M}_\psi^\theta \), \( \nu(\Lambda_\theta^{\text{con}}) = 0 \);
3. For any \((\nu, \nu_i) \in \mathcal{M}_\psi^\theta \times \mathcal{M}_{\psi \circ i}^{i(\theta)}\), the \( \Gamma \)-action on \((\Lambda_\theta^{(2)}, \nu \times \nu_i)\) is completely dissipative and non-ergodic;
4. For any \((\nu, \nu_i) \in \mathcal{M}_\psi^\theta \times \mathcal{M}_{\psi \circ i}^{i(\theta)}\), the \( a_\theta \)-action on \((\Omega_\theta, m_{\nu, \nu_i})\) is completely dissipative and non-ergodic.

**Disjoint dimensions phenomenon.** Let
\[
D_\Gamma^\theta = \left\{ \psi \in a^*_\theta : (\Gamma, \theta)\text{-proper}, \delta_\psi(\Gamma) = 1 \text{ and } \mathcal{P}_\psi(1) = \infty \right\}.
\]

This is in fact same as
\[
\left\{ \psi \in a^*_\theta : (\Gamma, \theta)\text{-proper}, \exists a (\Gamma, \psi)\text{-conformal measure, } \mathcal{P}_\psi(1) = \infty \right\}
\]
when \( \Gamma \) is a \( \theta \)-transverse subgroup (see Lemma 11.4).

Inspired by the entropy drop phenomenon proved by Canary-Zhang-Zimmer [9, Theorem 4.1] for \( \theta = i(\theta) \), we deduce from Theorem 1.4 the following disjointness of dimensions (Theorem 11.5), which turns out to be equivalent to the entropy drop phenomenon (Corollary 11.6):

**Corollary 1.10 (Disjoint dimensions).** Let \( \Gamma < G \) be a \( \theta \)-transverse subgroup. For any Zariski dense subgroup \( \Gamma_0 < \Gamma \) with \( \Lambda_\theta(\Gamma_0) \neq \Lambda_\theta(\Gamma) \), we have
\[
D_\Gamma^\theta \cap D_{\Gamma_0}^\theta = \emptyset.
\]

In the rank one case, this corollary says that if \( \Lambda(\Gamma_0) \neq \Lambda(\Gamma) \) and \( \Gamma_0 < \Gamma \) are of divergence type, that is, their Poincaré series diverge at the critical
exponents, then $\delta_\Gamma_0 < \delta_\Gamma$. We refer to [9] for a more detailed background on this phenomenon.

Remark 1.11. In fact, our proofs show Theorem 1.9 and Corollary 1.10 if $\Gamma$ is non-elementary, i.e., $\#\Lambda_\theta \geq 3$ and not necessarily Zariski dense. See Remark 10.3.

$\theta$-Anosov subgroups. A finitely generated subgroup $\Gamma < G$ is a $\theta$-Anosov subgroup if there exists $C > 0$ such that for all $\gamma \in \Gamma$,

$$\min_{\alpha \in \theta} \alpha(\mu) \geq C|\gamma| - C^{-1}$$

(1.8)

where $|\gamma|$ denotes the word length of $\gamma$ with respect to a fixed finite generating set of $\Gamma$ ([26], [15], [19], [20], [21]). All $\theta$-Anosov subgroups are $\theta$-transverse and $\Lambda_\theta = \Lambda_\theta^{con}$ ([16], [20]). We deduce the following from Theorem 1.4:

Theorem 1.12. Let $\Gamma < G$ be a $\theta$-Anosov subgroup. Suppose that there exists a $(\Gamma, \psi)$-conformal measure $\nu$ on $F_\theta$ for $\psi \in a_\theta^*$. We have:

1. The linear form $\psi$ is $(\Gamma, \theta)$-proper and $\psi \geq \psi_\Gamma^\theta$.
2. The following are equivalent to each other:
   (a) $\sum_{\gamma \in \Gamma} e^{-\psi(\mu(\gamma))} = \infty$ (resp. $\sum_{\gamma \in \Gamma} e^{-\psi(\mu(\gamma))} < \infty$);
   (b) $\nu(\Lambda_\theta) = 1$ (resp. $\nu(\Lambda_\theta) = 0$);
   (c) $\psi$ is $(\Gamma, \theta)$-critical (resp. $\psi$ is not $(\Gamma, \theta)$-critical).
3. For each $(\Gamma, \theta)$-critical $\psi \in a_\theta^*$, there exists a unique $(\Gamma, \psi)$-conformal measure, say, $\nu_\psi$, on $F_\theta$, which is necessarily supported on $\Lambda_\theta$. Moreover the $a_\theta$-action on $(\Omega_\theta, m_{\nu_\psi}, \nu_\psi \circ \cdot)$ is completely conservative and ergodic.

The equivalence $(a) \iff (b)$ in (2) answers a question asked by Sambarino [39, Remark 5.10].

Analogue of Ahlfors measure conjecture for $\theta$-Anosov groups. We denote by $Leb_\theta$ Lebesgue measure on $F_\theta$, which is the unique $K$-invariant probability measure on $F_\theta$. The following corollary is motivated by the Ahlfors measure conjecture [2].

Corollary 1.13. If $\Gamma < G$ is $\theta$-Anosov, then

either $\Lambda_\theta = F_\theta$ or $Leb_\theta(\Lambda_\theta) = 0$.

Moreover, in the former case, $\theta$ is the simple root of a rank one factor, say $G_0$, of $G$ and $\Gamma$ projects to a cocompact lattice of $G_0$.

See Theorem 11.1 for a more general version stated for a $\theta$-transverse subgroup.
Critical forms and conformal measures. We set
\[ T^\theta_{\Gamma} := \{ \psi \in a^\theta : \psi \text{ is } (\Gamma, \theta)\text{-critical} \}. \]
Note that \( D^\theta_{\Gamma} \subset T^\theta_{\Gamma} \) (Corollary 4.6). For \( \theta\)-Anosov subgroups, we further have \( T^\theta_{\Gamma} = D^\theta_{\Gamma} \), which is again same as the set of all \( \psi \in a^\theta \) for which there exists a \((\Gamma, \psi)\)-conformal measure supported on \( \Lambda_\theta \) (Lemma 12.3). Using Sambarino’s parametrization of the space of all conformal measures on \( \Lambda_\theta \) as \( \{ \delta_\psi = 1 \} \) [39, Theorem A], we deduce:

**Corollary 1.14.** For any \( \theta\)-Anosov subgroup \( \Gamma < G \), we have a one-to-one correspondence among

1. the set \( T^\theta_{\Gamma} \) of all \((\Gamma, \theta)\)-critical forms on \( a^\theta \);
2. the set of all unit vectors in \( \text{int}\ L^\theta_{\Gamma} \);
3. the set of all \( \Gamma \)-conformal measures supported on \( \Lambda_\theta \);
4. the set of all \( \Gamma \)-conformal measures on \( F^\theta_{\Gamma} \) of critical dimensions.

More precisely, for any \( \psi \in T^\theta_{\Gamma} \), there exists a unique unit vector \( u_\psi \in a^\theta \) such that \( \psi(u_\psi) = \psi^\theta_{\Gamma}(u_\psi) \); moreover \( u_\psi \in \text{int}\ L^\theta_{\Gamma} \). There also exists a unique \((\Gamma, \psi)\)-conformal measure \( \nu_\psi \) on \( F^\theta_{\Gamma} \), which is necessarily supported on \( \Lambda_\theta \). Moreover every \( \Gamma \)-conformal measure supported on \( \Lambda_\theta \) arises in this way.

**Corollary 1.15** (Disjoint critical dimensions). For any Zariski dense \( \theta\)-Anosov subgroups \( \Gamma_0 < \Gamma \) such that \( \Lambda_\theta(\Gamma_0) \neq \Lambda_\theta(\Gamma) \), we have
\[ T^\theta_{\Gamma} \cap T^\theta_{\Gamma_0} = \emptyset \quad \text{and} \quad \psi^\theta_{\Gamma_0} < \psi^\theta_{\Gamma} \text{ on } \text{int}\ L^\theta_{\Gamma}(\Gamma). \]

Indeed, the above two conditions are equivalent to each other by the vertical tangency of \( \psi^\theta_{\Gamma} \) (Theorem 12.2).

**Remark 1.16.** Related dichotomy properties for conformal measures were studied in [12], [6], [27], [13], [39], [9], etc. In particular, when \( \Gamma \) is \( \Pi \)-Anosov, Theorem 1.12 Corollaries 1.13 and 1.14 were proved by Lee-Oh [27 Theorems 1.3, 1.4]. The papers [12], [39], and [9] study conformal measures supported on the limit set \( \Lambda_\theta \) and the papers [6] and [13] study the role of directional conical sets in the ergodic behavior of conformal measures. Our focus on this paper is to address general conformal measures without restriction on their supports following [27] and to study the relationship between the dimensions of conformal measures and \( \theta \)-growth indicators so as to establish an analogue of Sullivan’s theorem (Theorem 1.1) and the analogue of the Ahlfors measure conjecture. We also emphasize that the \( \theta \)-growth indicator is first introduced in our paper. Notably, Theorem 1.7 provides a new locally compact Hausdorff space \( \Omega_\theta := \Gamma\backslash A^2_\theta \times a_\theta \) which is a non-wandering set for the Weyl chamber flow \( A_\theta \). This allows us to define Bowen-Margulis-Sullivan measures as in the rank one setting. Hence the dynamical properties of the Weyl chamber flow can be studied also in higher rank, fully recovering the original work of Hopf-Tsuji-Sullivan.

Finally, we mention that there is a plethora of examples of \( \theta \)-transverse subgroups which are not \( \theta \)-Anosov. First of all, any subgroup of \( \theta \)-Anosov
subgroups are $\theta$-transverse. For instance, a co-abelian subgroup of a $\theta$-Anosov subgroup of infinite index is $\theta$-transverse but not $\theta$-Anosov. The images of cusped Hitchin representations of geometrically finite Fuchsian groups by [7] are also $\theta$-transverse but not $\theta$-Anosov. Another important examples are self-joinings of geometrically finite subgroups of rank one Lie groups, that is, $\Gamma = (\prod_{i=1}^{k} \rho_{i})(\Delta) = \{(\rho_{i}(g))_{i} : g \in \Delta\}$ where $\Delta$ is a geometrically finite subgroup of a rank one simple real algebraic group $G_{0}$ and $\rho_{i} : \Delta \to G_{i}$ is a type-preserving isomorphism onto its image $\rho_{i}(\Delta)$ which is a geometrically finite subgroup of a rank one simple real algebraic group $G_{i}$ for each $1 \leq i \leq k$. It follows from [42, Theorem 3.3] and [11, Theorem A.4] (see also [44, Theorem 0.1]) that there exists a $\rho_{i}$-equivariant homeomorphism between the limit set of $\Delta$ and the limit set of $\rho_{i}(\Delta)$ for each $1 \leq i \leq k$. This implies that $\Gamma$ is $\Pi$-transverse.

Organization.

- In section 2, we introduce the notion of convergence of elements of $G$ to those of $\mathcal{F}_{\theta}$ and present some basic lemmas which will be used in the proof of our main theorems.
- In section 3, we define the $\theta$-growth indicator $\psi_{\Gamma}^{\theta}$ for a $\theta$-discrete subgroup $\Gamma \leq G$. Properties of the $\theta$-growth indicator and its relationship with Quint’s growth indicator [33] are also discussed.
- In section 4, we introduce $(\Gamma, \theta)$-proper linear forms and $(\Gamma, \theta)$-critical linear forms and discuss properties of their critical exponents.
- In section 5, we define the $\theta$-limit set and the $\theta$-conical set of $\Gamma$. For $\theta$-regular subgroups, we show that the $\theta$-conical set is a subset of the $\theta$-limit set and construct conformal measures supported on the $\theta$-limit set for each $\psi \in \mathcal{D}_{\theta}^{\Gamma}$.
- In section 6, we prove that for $\theta$-transverse subgroups, $\theta$-shadows with bounded width have bounded multiplicity, which is one of the key technical ingredients of our main results.
- In section 7, we show that if $\Gamma$ is a $\theta$-transverse subgroup, the dimension of a $\Gamma$-conformal measure is at least $\psi_{\Gamma}^{\theta}$ (Theorem 7.1).
- In section 8, we prove the zero-one law for the $\nu$-size of the conical set depending on whether or not the associated Poincaré series converges at its dimension (Theorem 8.1).
- In section 9, we prove that a $\theta$-transverse subgroup $\Gamma$ acts properly discontinuously on $\Lambda_{\theta}^{(2)} \times a_{\theta}$ and define Bowen-Margulis-Sullivan measures on the space $\Omega_{\theta} = \Gamma \backslash \Lambda_{\theta}^{(2)} \times a_{\theta}$. For any $(\Gamma, \theta)$-proper form $\varphi$, we also show that the $\varphi$-twisted $\Gamma$-action on $\Lambda_{\theta}^{(2)} \times \mathbb{R}$ is properly discontinuous and gives rise to a trivial vector bundle $\Omega_{\theta} \to \Omega_{\varphi} = \Gamma \backslash \Lambda_{\theta}^{(2)} \times \mathbb{R}$. 
In section 10, we expand the equivalence between dichotomies to conservativity and ergodicity of the $a_\theta$-action on $\Omega_\theta$, proving Theorem 1.9. We also explain how to deduce Theorem 1.4 from Theorems 7.1 and 8.1.

In section 11, we discuss several consequences of Theorem 8.1, including disjoint dimension phenomenon.

Finally, in section 12 we discuss how our theorems are applied for $\theta$-Anosov groups. We also prove Corollary 1.13.

Acknowledgement. We would like to thank Jean-François Quint for useful conversations about Lemma 3.13.

2. Convergence in $G \cup F_\theta$.

In the whole paper, let $G$ be a connected semisimple real algebraic group. Let $P < G$ be a minimal parabolic subgroup with a fixed Langlands decomposition $P = MAN$ where $A$ is a maximal real split torus of $G$, $M$ is the maximal compact subgroup of $P$ commuting with $A$ and $N$ is the unipotent radical of $P$. Let $g$ and $a$ respectively denote the Lie algebras of $G$ and $A$. Fix a positive Weyl chamber $a^+ < a$ so that $\log N$ consists of positive root subspaces and set $A^+ = \exp a^+$. We fix a maximal compact subgroup $K < G$ such that the Cartan decomposition $G = KA^+K$ holds. We denote by

$$
\mu : G \to a^+
$$

the Cartan projection defined by the condition $g \in K \exp \mu(g)K$ for $g \in G$. Let $X = G/K$ be the associated Riemannian symmetric space, and set $o = [K] \in X$. Fix a $K$-invariant norm $\| \cdot \|$ on $g$ induced from the Killing form on $g$ and let $d$ denote the Riemannian metric on $X$ induced by $\| \cdot \|$.

Lemma 2.1. [3, Lemma 4.6] For any compact subset $Q \subset G$, there exists $C = C(Q) > 0$ such that for all $g \in G$,

$$
\sup_{q_1, q_2 \in Q} \| \mu(q_1 q g q_2) - \mu(g) \| \leq C.
$$

Let $\Phi = \Phi(g, a)$ denote the set of all roots, $\Phi^+ \subset \Phi$ the set of all positive roots, and $\Pi \subset \Phi^+$ the set of all simple roots. We denote by $N_K(A)$ and $C_K(A)$ the normalizer and centralizer of $A$ in $K$ respectively. Consider the Weyl group $W = N_K(A)/C_K(A)$. Fix an element

$$
w_0 \in N_K(A)
$$

representing the longest Weyl element so that $\text{Ad}_{w_0} a^+ = -a^+$ and $w_0^{-1} = w_0$. Hence the map

$$
i = -\text{Ad}_{w_0} : a \to a
$$

defines an involution of $a$ preserving $a^+$; this is called the opposition involution. It induces a map $\Phi \to \Phi$ preserving $\Pi$, for which we use the same notation $i$, such that $i(\alpha) \circ \text{Ad}_{w_0} = -\alpha$ for all $\alpha \in \Phi$. We have

$$
\mu(g^{-1}) = i(\mu(g)) \quad \text{for all } g \in G.
$$

(2.1)
In the rest of the paper, we fix a non-empty subset $\theta \subset \Pi$. Let $P_\theta$ denote a standard parabolic subgroup of $G$ corresponding to $\theta$; that is, $P_\theta$ is generated by $MA$ and all root subgroups $U_\alpha$, $\alpha \in \Phi^+ \cup [\Pi - \theta]$ where $[\Pi - \theta]$ denotes the set of all roots in $\Phi$ which are $\mathbb{Z}$-linear combinations of $\Pi - \theta$. Hence $P_\Pi = P$. The subgroup $P_\theta$ is equal to its own normalizer; for $g \in G$, $gP_\theta g^{-1} = P_\theta$ if and only if $g \in P_\theta$. Let

$$a_\theta = \bigcap_{\alpha \in \Pi - \theta} \ker \alpha, \quad a_\theta^+ = a_\theta \cap a^+, \quad A_\theta = \exp a_\theta, \quad A_\theta^+ = \exp a_\theta^+.$$  

Let

$$p_\theta : a \to a_\theta$$

denote the projection invariant under $w \in W$ fixing $a_\theta$ pointwise.

Let $L_\theta$ denote the centralizer of $A_\theta$; it is a Levi subgroup of $P_\theta$ and $P_\theta = L_\theta N_\theta$ where $N_\theta = R_u(P_\theta)$ is the unipotent radical of $P_\theta$. We set $M_\theta = K \cap P_\theta \subset L_\theta$. We may then write $L_\theta = A_\theta S_\theta$ where $S_\theta$ is an almost direct product of a connected semisimple real algebraic subgroup and a compact subgroup. Then $B_\theta = S_\theta \cap A$ is a maximal $\mathbb{R}$-split torus of $S_\theta$ and $\Pi - \theta$ is the set of simple roots for $(\text{Lie} S_\theta, \text{Lie} B_\theta)$. Letting $B_\theta^+ = \{b \in B_\theta : \alpha(\log b) \geq 0 \text{ for all } \alpha \in \Pi - \theta\}$, we have the Cartan decomposition of $S_\theta$:

$$S_\theta = M_\theta B_\theta^+ M_\theta.$$

Any $u \in a$ can be written as $u = u_1 + u_2$ for unique $u_1 \in a_\theta$ and $u_2 \in \log B_\theta$, and we have $p_\theta(u) = u_1$. In particular, we have

$$A = A_\theta B_\theta \quad \text{and} \quad A_\theta^+ \subset A_\theta^+ B_\theta^+.$$

We denote by $a_\theta^* = \text{Hom}(a_\theta, \mathbb{R})$ the dual space of $a_\theta$. It can be identified with the subspace of $a^*$ which is $p_\theta$-invariant: $a_\theta^* = \{\psi \in a^* : \psi \circ p_\theta = \psi\}$; so for $\theta_1 \subset \theta_2$, we have $a_{\theta_1}^* \subset a_{\theta_2}^*$. 

**The $\theta$-boundary $\mathcal{F}_\theta$ and convergence to $\mathcal{F}_{\theta}$.** We set

$$\mathcal{F}_\theta = G/P_\theta \quad \text{and} \quad \mathcal{F} = G/P.$$  

Let

$$\pi_\theta : \mathcal{F} \rightarrow \mathcal{F}_\theta$$

denote the canonical projection map given by $gP \mapsto gP_\theta$, $g \in G$. We set

$$\xi_\theta = [P_\theta] \in \mathcal{F}_\theta.$$  

By the Iwasawa decomposition $G = KP = KAN$, the subgroup $K$ acts transitively on $\mathcal{F}_\theta$, and hence

$$\mathcal{F}_\theta \simeq K/M_\theta.$$  

We consider the following notion of convergence of a sequence in $G$ to an element of $\mathcal{F}_\theta$. 
Definition 2.2. For a sequence \( g_i \in G \) and \( \xi \in \mathcal{F}_\theta \), we write \( \lim_{i \to \infty} g_i = \lim g_{i,\infty} = \xi \) and say \( g_i \) (or \( g_{i,\infty} \in X \)) converges to \( \xi \) if

- \( \min_{\alpha \in \Theta} \alpha(\mu(g_i)) \to \infty \); and
- \( \lim_{i \to \infty} \kappa_{g_i}\xi_\theta = \xi \) in \( \mathcal{F}_\theta \) for some \( \kappa_{g_i} \in K \) such that \( g_i \in \kappa_{g_i}A^+K \).

Points in general position. Let \( P_\theta^+ \) be the standard parabolic subgroup of \( G \) opposite to \( P_\theta \) such that \( P_\theta \cap P_\theta^+ = L_\theta \). We have \( P_\theta^+ = w_0P_{i(\theta)}w_0^{-1} \) and hence

\[
\mathcal{F}_{i(\theta)} = G/P_\theta^+.
\]

In particular, if \( \theta \) is symmetric in the sense that \( \theta = i(\theta) \), then \( \mathcal{F}_\theta = G/P_\theta^+ \).

Let \( N_\theta^+ \) denote the unipotent radical of \( P_\theta^+ \). The set \( N_\theta^+P_\theta \) is a Zariski open and dense subset of \( G \). In particular, \( N_\theta^+\xi_\theta \cap hN_\theta^+\xi_\theta \neq \emptyset \) for any \( h \in G \).

The \( G \)-orbit of \( (P_\theta, P_\theta^+) \) is the unique open \( G \)-orbit in \( G/P_\theta \times G/P_\theta^+ \) under the diagonal \( G \)-action.

Definition 2.3. Two elements \( \xi \in \mathcal{F}_\theta \) and \( \eta \in \mathcal{F}_{i(\theta)} \) are said to be in general position if \( (\xi, \eta) \in G.(P_\theta, w_0P_{i(\theta)}) = G.(P_\theta, P_\theta^+) \), i.e., \( \xi = gP_\theta \) and \( \eta = gw_0P_{i(\theta)} \) for some \( g \in G \).

We set

\[
\mathcal{F}_\theta^{(2)} = \{ (\xi, \eta) \in \mathcal{F}_\theta \times \mathcal{F}_{i(\theta)} : \xi, \eta \text{ are in general position} \},
\]

which is the unique open \( G \)-orbit in \( \mathcal{F}_\theta \times \mathcal{F}_{i(\theta)} \). It follows from the identity \( P_\theta^+ = N_\theta^+P_\theta \cap P_\theta^+ \) that

\[
(gP_\theta, P_\theta^+) \in \mathcal{F}_\theta^{(2)} \quad \text{if and only if} \quad g \in N_\theta^+P_\theta.
\]

Basic lemmas. We generalize [28, Lemmas 2.9-11] from \( \theta = I \) to a general \( \theta \) as follows. For subsets \( S_i \subset G \), we often write \( g = g_1g_2g_3 \in S_1S_2S_3 \) to mean that \( g_i \in S_i \) for each \( i \), in addition to \( g = g_1g_2g_3 \).

Lemma 2.4. Consider a sequence \( g_i = k_ia_ih_i^{-1} \) where \( k_i \in K \), \( a_i \in A^+ \), and \( h_i \in G \). Suppose that \( k_i \to k_0 \in K \), \( h_i \to h_0 \in G \), and \( \min_{\alpha \in \Theta} \alpha(\log a_i) \to \infty \), as \( i \to \infty \). Then for any \( \xi \in h_0N_\theta^+\xi_\theta \) (i.e., \( \xi \) is in general position with \( h_0P_\theta^+ \)), we have

\[
\lim_{i \to \infty} g_i\xi = k_0\xi_\theta.
\]

Proof. Since \( h_i^{-1}\xi \) converges to the element \( h_0^{-1}\xi \in N_\theta^+\xi_\theta \) by the hypothesis and \( N_\theta^+\xi_\theta \subset \mathcal{F}_\theta \) is open, we have \( h_i^{-1}\xi \in N_\theta^+\xi_\theta \) for all large \( i \). Hence we can write \( h_i^{-1}\xi = n_i\xi_\theta \) with \( n_i \in N_\theta^+ \) uniformly bounded. Since \( \min_{\alpha \in \Theta} \alpha(\log a_i) \to \infty \) and \( n_i \in N_\theta^+ \) is uniformly bounded, we have \( a_in_i^{-1} \to e \) as \( i \to \infty \). Therefore the sequence \( a_ih_i^{-1}\xi = a_in_i^{-1}\xi_\theta \) converges to \( \xi_\theta \). Hence we have

\[
\lim_{i \to \infty} g_i\xi = \lim_{i \to \infty} k_i(a_ih_i^{-1}\xi) = k_0\xi_\theta.
\]

\[\square\]
Corollary 2.5. If $w \in N_K(A)$ is such that $mw \in N^+_\theta P_\theta$ for some $m \in M_\theta$, then $w \in M_\theta$. In particular, if $wP_\theta$ and $P^+_\theta$ are in general position, then $w \in M_\theta$.

Proof. Choose any sequence $a_i \in A^+_\theta$ such that $\min_{\alpha \in \theta} \alpha (\log a_i) \to \infty$. Since $mw_i \xi_\theta \in N^+_\theta \xi_\theta$, we deduce from Lemma 2.4 that $a_i mw_i \xi_\theta$ converges to $\xi_\theta$ as $i \to \infty$. On the other hand, since $w \in N_K(A), A \subset P_\theta$ and $m \in M_\theta$, we have $a_i mw_i \xi_\theta = mw_i^{-1} a_i w_i \xi_\theta = mw_i \xi_\theta$ for all $i$. Hence $mw_i \xi_\theta = \xi_\theta$. Since $m \in M_\theta$, this implies $w \xi_\theta = \xi_\theta$ and hence $w \in P_\theta \cap K = M_\theta$. □

It turns out that the convergence of $g_i \to \xi$ is equivalent to $g_i p \to \xi$ for any $p \in X$. More generally, we have

Lemma 2.6. If a sequence $g_i \in G$ converges to $\xi \in \mathcal{F}_\theta$ and $p_i \in X$ is a bounded sequence, then

$$\lim_{i \to \infty} g_i p_i = \xi.$$ 

Proof. Let $g'_i \in G$ be such that $g'_i p = p_i$; then $g'_i$ is bounded. Since $\lim g_i = \xi$, we may write $g_i = k_i a_i l_i^{-1}$ with $k_i, l_i \in K$ and $a_i \in A^+$ where $\min_{\alpha \in \theta} \alpha (\log a_i) \to \infty$, and $k_i \xi_\theta \to \xi$ as $i \to \infty$. Write $g_i g'_i = k'_i a'_i (l'_i)^{-1} \in KA^+ K$. Since $g'_i$ is bounded, $\lim_{i \to \infty} \min_{\alpha \in \theta} \alpha (\log a'_i) = \infty$, by Lemma 2.1. Let $q \in K$ be a limit of the sequence $q_i := k_i^{-1} k'_i$. By passing to a subsequence, we may assume that $q_i \to q$. Since $d(o, p_i) = d(g_i o, g_i p_i) = d(o, a_i^{-1} q_i a'_i o)$, the sequence $h_i^{-1} := a_i^{-1} q_i a'_i$ is bounded. Passing to a subsequence, we may assume that $h_i$ converges to some $h_0 \in G$. Choose any $\eta \in N^+_\theta \xi_\theta \cap h_0 N^+_\theta \xi_\theta$. By Lemma 2.4 we have

$$\lim_{i \to \infty} a_i h_i^{-1} \eta = \xi_\theta \quad \text{and} \quad \lim_{i \to \infty} q_i a'_i \eta = q \xi_\theta.$$ 

Since $a_i h_i^{-1} = q_i a'_i$, it follows that $q \xi_\theta = \xi_\theta$; so $q \in K \cap P_\theta$. Hence $\xi = \lim k_i \xi_\theta = \lim k'_i \xi_\theta$. It follows that $\lim g_i p_i = \xi$. □

Lemma 2.7. If a sequence $g_i \in G$ converges to $g$ and a sequence $a_i \in A^+$ satisfies $\min_{\alpha \in \theta} \alpha (\log a_i) \to \infty$ as $i \to \infty$, then for any $p \in X$, we have

$$\lim_{i \to \infty} g_i a_i p = g \xi_\theta.$$ 

Proof. By Lemma 2.6, it suffices to consider the case when $p = o$. Write $g_i a_i = k_i b_i l_i^{-1}$ with $k_i, l_i \in K$ and $b_i \in A^+$. Since the sequence $g_i a_i$ is bounded, $\lim_{i \to \infty} \min_{\alpha \in \theta} \alpha (\log b_i) = \infty$. Let $k_0$ be a limit of the sequence $k_i$; without loss of generality, we may assume that $k_i$ converges to $k_0$ as $i \to \infty$. Then $\lim_{i \to \infty} g_i a_i o = k_0 \xi_\theta$. We may also assume that $\ell_i$ converges to some $\ell_0 \in K$. Choose $\xi \in \ell_0 N^+_\theta \xi_\theta \cap N^+_\theta \xi_\theta$. Then by Lemma 2.4 as $i \to \infty$, $g_i a_i \xi \to k_0 \xi_\theta$ and $a_i \xi \to \xi_\theta$. Since $g_i$ converges to $g$, this implies that $k_0 \xi_\theta = g \xi_\theta$. This finishes the proof. □
3. Growth indicators

Let \( \Gamma < G \) be a Zariski dense discrete subgroup. We set
\[
\mu_\theta := p_\theta \circ \mu : G \to a_\theta^+.
\]
(3.1)

**Definition 3.1.** We say that \( \Gamma \) is \( \theta \)-discrete if the restriction \( \mu_\theta | \Gamma : \Gamma \to a_\theta^+ \) is proper.

The \( \theta \)-discreteness of \( \Gamma \) implies that \( \mu_\theta(\Gamma) \) is a closed discrete subset of \( a_\theta^+ \). Indeed, \( \Gamma \) is \( \theta \)-discrete if and only if the counting measure on \( \mu_\theta(\Gamma) \) weighted with multiplicity is a Radon measure on \( a_\theta^+ \).

**Definition 3.2** (\( \theta \)-growth indicator). For a \( \theta \)-discrete subgroup \( \Gamma < G \), we define the \( \theta \)-growth indicator \( \psi^\theta_\Gamma : a_\theta \to [-\infty, \infty] \) as follows: if \( u \in a_\theta \) is non-zero,
\[
\psi^\theta_\Gamma(u) = \|u\| \inf_{\tau^\theta_C} \tau^\theta_C
\]
where \( C \subset a_\theta \) ranges over all open cones containing \( u \), and \( \psi^\theta_\Gamma(0) = 0 \). Here \( -\infty \leq \tau^\theta_C \leq \infty \) denotes the abscissa of convergence of the series \( P^\theta_C(s) = \sum_{\gamma \in \Gamma, \mu_\theta(\gamma) \in C} e^{-s\|\mu_\theta(\gamma)\|} \), that is,
\[
\tau^\theta_C = \sup \{ s \in \mathbb{R} : P^\theta_C(s) = \infty \} = \inf \{ s \in \mathbb{R} : P^\theta_C(s) < \infty \}.
\]

This definition is independent of the choice of a norm on \( a_\theta \). For \( \theta = \Pi \), we set
\[
\psi^\Pi_\Gamma := \psi^\Pi_\Gamma.
\]

The main goal of this section is to establish the following properties of \( \psi^\theta_\Gamma \) for a general \( \theta \subset \Pi \): for \( \theta = \Pi \), this theorem is due to Quint [33, Theorem 1.1.1].

**Theorem 3.3.** Let \( \Gamma < G \) be a \( \theta \)-discrete subgroup.

1. \( \psi^\theta_\Gamma < \infty \).
2. \( \psi^\theta_\Gamma \) is a homogeneous, upper semi-continuous and concave function.
3. \( \mathcal{L}_\theta = \{ \psi^\theta_\Gamma \geq 0 \}, \psi^\theta_\Gamma = -\infty \) outside \( \mathcal{L}_\theta \) and \( \psi^\theta_\Gamma > 0 \) on \( \text{int} \mathcal{L}_\theta \).

Here, \( \mathcal{L}_\theta \subset a_\theta^+ \) denotes the \( \theta \)-limit cone of \( \Gamma \), which is the asymptotic cone of \( \mu_\theta(\Gamma) \):
\[
\mathcal{L}_\theta = \{ \lim t_i \mu_\theta(\gamma_i) : \gamma_i \in \Gamma, t_i \to 0 \}.
\]
(3.3)

We set \( \mathcal{L} = \mathcal{L}_\Pi \), which is the usual limit cone. By [3] Sections 1.2, 4.6], \( \mathcal{L} \) is a convex cone with non-empty interior and \( \mu(\Gamma) \) is within a bounded distance from \( \mathcal{L} \). We have
\[
\mathcal{L} = \{ \psi_\Gamma \geq 0 \}, \quad \psi_\Gamma > 0 \text{ on } \text{int} \mathcal{L}
\]
and \( \psi_\Gamma = -\infty \) outside \( \mathcal{L} \) [33, Theorem 1.1.1]. Noting that \( \mathcal{L}_\theta = p_\theta(\mathcal{L}) \), we get:

**Lemma 3.4.** The \( \theta \)-limit cone \( \mathcal{L}_\theta \) is a convex cone in \( a_\theta^+ \) with non-empty interior and \( \mu_\theta(\Gamma) \) is within a bounded distance from \( \mathcal{L}_\theta \).
ψ_Γ^θ < ∞ and θ-critical exponent. In this subsection, we show Theorem 3.3(1), that is, ψ_Γ^θ does not take +∞-value. This will be achieved by proving δ_Γ^θ < ∞ (Proposition 3.7) where

\[ -∞ ≤ δ_Γ^θ ≤ ∞ \]
denotes the abscissa of convergence of the series \( s \mapsto \sum_{γ ∈ Γ} e^{-s\|μ_θ(γ)\|} \). For θ = Π, we have 0 < δ_Γ ≤ δ_Π < ∞ [33, Theorem 4.2.2]. Since \( \|μ_θ(g)\| ≤ \|μ(g)\| \) for all \( g ∈ G \) and hence \( \sum_{γ ∈ Γ} e^{-s\|μ(γ)\|} ≤ \sum_{γ ∈ Γ} e^{-s\|μ_θ(γ)\|} \) for all \( s ≥ 0 \), we have

\[ 0 < δ_Γ ≤ δ_Γ^θ. \] (3.5)

Lemma 3.5. If Γ is θ-discrete, then

\[ δ_Γ^θ = \limsup_{t→∞} \frac{1}{t} \# \{ γ ∈ Γ : \|μ_θ(γ)\| < t \} ∈ (0, ∞]. \]

Proof. For \( x ∈ a_θ \), we denote by \( D_x \) the Dirac mass at \( x \). Since \( P_γ ∈ Γ D_µ_θ(γ) \) is a Radon measure on \( a_θ^+ \) and \( δ_Γ^θ > 0 \) by (3.5), it follows from [33, Lemma 3.1.1]. \( \square \)

For a general discrete subgroup Γ < G, \( δ_Γ^θ \) may be infinite (e.g., Γ = Γ_1 × Γ_2 where Γ_i is an infinite discrete subgroup of G_i for both \( i = 1, 2 \)). Since \( r_Γ^θ ≤ δ_Γ^θ \) for all cones \( C \) in \( a_θ \), we have

\[ \sup_{u ∈ a_θ,\|u\|=1} ψ_Γ^θ(u) ≤ δ_Γ^θ. \]

Hence Theorem 3.3(1) follows once we show the that \( δ_Γ^θ < ∞ \) for any θ-discrete subgroup Γ < G as in Proposition 3.7.

\[ \begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1.png}
\caption{G = PSL_3(\mathbb{R}) and θ = \{α_1\}.}
\end{figure} \]

Lemma 3.6. If \( p_θ|_{a^+} \) is a proper map (e.g., G is simple), then

\[ δ_Γ^θ < ∞ \]

for any discrete subgroup Γ < G. In particular, if G is simple, any discrete subgroup Γ < G is θ-discrete.
Proof. First, observe that if $G$ is simple, then the angle between any two walls of $a^+$ is strictly smaller than $\pi/2$ and hence $p_\theta|_{a^+}$ is a proper map (see Figure 1). Now, if $p_\theta|_{a^+}$ is a proper map, then for some constant $C > 1$, we have

$$C^{-1}\|u\| \leq \|p_\theta(u)\| \leq C\|u\|$$

for all $u \in a^+$. Hence $\delta_\Gamma < \infty$ implies that $\delta_\Gamma^\theta < \infty$. \hfill $\square$

It follows from the definition of $\delta_\Gamma^\theta$ that the finiteness of $\delta_\Gamma^\theta$ implies the $\theta$-discreteness of $\Gamma$. Indeed, the converse holds as well from which Theorem 3.3(1) follows.

**Proposition 3.7.** We have

$\Gamma$ is $\theta$-discrete if and only if $\delta_\Gamma^\theta < \infty$.

**Proof.** It suffices to show that the $\theta$-discreteness of $\Gamma$ implies $\delta_\Gamma^\theta < \infty$. Write $G = G_1G_2$ as an almost direct product of semisimple real algebraic groups where $G_1$ is the smallest group such that $\theta$ is contained in the set of simple roots for $(g_1, a^+_1 = a^+ \cap g_1)$. Then $\mu_\theta(\Gamma) \subset a^+_1 \subset a^+$. Since the kernel of $p_\theta|_{\mu(\Gamma)}$ contains $\mu(\Gamma \cap (\{e\} \times G_2))$, the properness hypothesis implies that $\Gamma \cap (\{e\} \times G_2)$ is finite. By passing to a subgroup of finite index, we may assume that $\Gamma \cap (\{e\} \times G_2)$ is trivial. The properness of $\mu_\theta|_\Gamma$ also implies that the projection of $\Gamma$ to $G_1$ is a discrete subgroup, which we denote by $\Gamma_1$. Since there exists a unique element, say, $\sigma(\gamma_1) \in G_2$ such that $(\gamma_1, \sigma(\gamma_1)) \in \Gamma$ for each $\gamma_1 \in \Gamma_1$, we get a faithful representation $\sigma : \Gamma_1 \rightarrow G_2$, and $\Gamma$ is of the form $\{(\gamma_1, \sigma(\gamma_1)) : \gamma \in \Gamma_1\}$. Since $\mu_\theta(\gamma) = \mu_\theta(\gamma_1)$ for $\gamma = (\gamma_1, \sigma(\gamma_1)) \in \Gamma$, we have

$$\delta_\Gamma^\theta = \delta_{\Gamma_1}^\theta.$$ 

Hence we may assume without loss of generality that $\theta$ contains at least one root of each simple factor of $G$. Since the restriction $p_\theta : a^+ \cap \text{Lie}G_0 \rightarrow a^+ \cap \text{Lie}G_0$ is a proper map for each simple factor $G_0$ of $G$ as mentioned before, it follows that $p_\theta$ is a proper map. Hence the claim $\delta_\Gamma^\theta < \infty$ follows by Lemma 3.6. \hfill $\square$

**Concavity of $\psi_\Gamma^\theta$.** The growth indicator $\psi_\Gamma^\theta$ is clearly a homogeneous and upper semi-continuous function [33, Lemma 3.1.7]. It is also a concave function, but its proof requires the following lemma, which is proved in [33] Proposition 2.3.1] for $\theta = \Pi$.

**Lemma 3.8.** Suppose that $\Gamma$ is $\theta$-discrete. Then there exists a map $\pi : \Gamma \times \Gamma \rightarrow \Gamma$ satisfying the following:

1. there exists $\kappa \geq 0$ such that for every $\gamma_1, \gamma_2 \in \Gamma$,

$$\|\mu_\theta(\pi(\gamma_1, \gamma_2)) - \mu_\theta(\gamma_1) - \mu_\theta(\gamma_2)\| < \kappa; \text{ and}$$

$$\|\mu_\theta(\pi(\gamma_1, \gamma_2)) - \mu_\theta(\gamma_1) - \mu_\theta(\gamma_2)\| < \kappa.$$
(2) for every $R \geq 0$, there exists a finite subset $H$ of $\Gamma$ such that for $\gamma_1, \gamma_1', \gamma_2, \gamma_2' \in \Gamma$ with $\|\mu_\theta(\gamma_i) - \mu_\theta(\gamma_i')\| \leq R$ for $i = 1, 2$, 
\[ \pi(\gamma_1, \gamma_2) = \pi(\gamma_1', \gamma_2') \Rightarrow \gamma_1' \in \gamma_1 H \text{ and } \gamma_2' \in H \gamma_2. \]

Proof. Since $p_\theta$ is norm-decreasing, (1) follows from [33 Proposition 2.3.1(1)]. By the proof of [33 Proposition 2.3.1(2)], the claim (2) holds if we set $H$ to be the subset consisting of all elements $\gamma \in \Gamma$ such that $\mu_\theta(\gamma) < R'$ for some $R' > 0$ depending only on $R$. Since $\Gamma$ is $\Theta$-discrete, this subset $H$ is finite, as desired. \hfill \Box

**Proposition 3.9.** If $\Gamma$ is $\Theta$-discrete, then $\psi_\Gamma^\Theta$ is concave.

Proof. By Lemma 3.8, the counting measure $\sum_{\gamma \in \Gamma} D_{\mu_\theta(\gamma)}$ is of concave growth (see [33 Section 3.2] for details). It follows from [33 Theorem 3.2.1] that $\psi_\Gamma^\Theta$ is concave. \hfill \Box

**Definition 3.10.** A linear form $\psi \in a_\theta^*$ is said to be tangent to $\psi_\Gamma^\Theta$ (at $u \in a_\theta^* - \{0\}$) if $\psi \geq \psi_\Gamma^\Theta$ on $a_\theta^*$ and $\psi(u) = \psi_\Gamma^\Theta(u)$.

By the supporting hyperplane theorem, we have the following corollary:

**Corollary 3.11.** For any $u \in \text{int} \mathcal{L}_\theta$, there exists a linear form $\psi \in a_\theta^*$ tangent to $\psi_\Gamma^\Theta$ at $u$.

**Positivity of $\psi_\Gamma^\Theta$.** By Lemma 3.4, we have $\psi_\Gamma^\Theta = -\infty$ outside $\mathcal{L}_\theta$. If $\Theta \supset \theta$, then any $\theta$-discrete $\Gamma$ is $\Theta$-discrete as well. The following lemma shows how $\psi_\Gamma^\Theta$ is related to $\psi_\Gamma$ from which Theorem 3.3(3) follows:

**Lemma 3.12.** For $\Theta \supset \theta$, let $p_\theta = p_\theta|_{a_\Theta} : a_\Theta \to a_\theta$ by abuse of notation. For any $\theta$-discrete $\Gamma \subset G$, we have 
\[ \psi_\Gamma^\Theta \circ p_\theta \geq \psi_\Gamma \text{ on } a_\Theta. \] (3.6)

In particular, 
\[ \psi_\Gamma^\Theta \geq 0 \text{ on } \mathcal{L}_\theta \text{ and } \psi_\Gamma^\Theta > 0 \text{ on } \text{int} \mathcal{L}_\theta. \] (3.7)

Proof. By (3.4) and the homogeneity, it suffices to prove (3.6) for a unit vector $u \in \mathcal{L}_\theta$. Let $v \in p_\theta^{-1}(u) \cap a_\Theta$. Let $\mathcal{C} \subset a_\theta$ be an open cone containing $u$. For each $\varepsilon > 0$, set 
\[ \mathcal{C}(v, \varepsilon) := \left\{ w \in a_\Theta : p_\theta(w) \neq 0 \text{ and } \left\| \frac{w}{\|p_\theta(w)\|} - v \right\| < \varepsilon \right\}. \] (3.8)

Since $\|p_\theta(v)\| = \|u\| = 1$, $\mathcal{C}(v, \varepsilon)$ is an open cone containing $v$. In the following, let $\varepsilon > 0$ be small enough so that $\mathcal{C}(v, \varepsilon) \subset p_\theta^{-1}(\mathcal{C})$.

Then for all $s \in \mathbb{R}$, we have 
\[ \sum_{\gamma \in \Gamma, \mu_\theta(\gamma) \in \mathcal{C}(v, \varepsilon)} e^{-s\|\mu_\theta(\gamma)\|} \leq \sum_{\gamma \in \Gamma, \mu_\theta(\gamma) \in \mathcal{C}(v, \varepsilon)} e^{-s\|v\| - \|s\|\|\mu_\theta(\gamma)\|} \]
\[ \leq \sum_{\gamma \in \Gamma, \mu_\theta(\gamma) \in \mathcal{C}} e^{-s\|v\| - \|s\|\|\mu_\theta(\gamma)\|}. \]
Hence we have
\[ \tau_C^{\Theta(v, \varepsilon)} \leq (\|v\| - \varepsilon)^{-1} \tau_C^\theta. \]
Therefore we have
\[ \psi^{\Theta}(v) \leq \|v\| \tau_C^{\Theta(v, \varepsilon)} \leq \|v\| (\|v\| - \varepsilon)^{-1} \tau_C^\theta. \]
Taking \( \varepsilon \to 0 \) yields that
\[ \psi^{\Theta}(v) \leq \tau_C^\theta. \]

Since \( C \subset a_\Theta \) is an arbitrary open cone in \( a_\theta \) containing \( u \), it follows that
\[ \psi^{\Theta}(v) \leq \psi^{\Theta}(u), \]
and hence (3.6) is proved. Last claim follows the from (3.4) and (3.6) applied to \( \Theta = \Pi \). \( \Box \)

Comparison between \( \psi^{\theta}_\Gamma \) and \( \psi^{\Theta}_\Gamma \). Note that the properness of \( p_\theta | L_\theta \) implies the \( \theta \)-discreteness of \( \Gamma \) as \( \mu(\Gamma) \) is within a bounded distance from \( L_\theta \).

The following lemma is to appear in [14] in a more general context.

Lemma 3.13. If \( p_\theta | L \) is a proper map (e.g., \( G \) is simple), then for any \( \Theta \supset \theta \) and for any \( u \in a_\theta \),
\[ \psi^{\theta}_\Gamma(u) = \max_{v \in p^{-1}_\theta(u)} \psi^{\Theta}_\Gamma(v) \]  (3.9)
where \( p_\theta = p_\theta | a_\theta \) by abuse of notation.

Proof. Suppose that \( p_\theta | L : L \to a_\theta \) is a proper map. By Lemma 3.12, it suffices to consider a unit vector \( u \in L_\theta \) with \( \psi^{\theta}_\Gamma(u) > 0 \). Since \( p^{-1}_\theta(u) \cap L_\Theta \) is a compact subset and \( \psi^{\Theta}_\Gamma \) is upper semi-continuous, we have
\[ \sup_{v \in p^{-1}_\theta(u)} \psi^{\Theta}_\Gamma(v) = \max_{v \in p^{-1}_\theta(u) \cap L_\Theta} \psi^{\Theta}_\Gamma(v). \]

For all sufficiently small \( \varepsilon > 0 \) and each \( v \in p^{-1}_\theta(u) \), there exists \( 0 < \varepsilon_v < \varepsilon \) such that
\[ \|v\| \tau_C^{\Theta(v, \varepsilon_v)} < \psi^{\Theta}_\Gamma(v) + \varepsilon \]  (3.10)
where \( C(v, \varepsilon_v) \) is as defined in (3.8). Since \( p^{-1}_\theta(u) \cap L_\Theta \) is compact, there exist \( v_1, \ldots, v_n \in p^{-1}_\theta(u) \) such that
\[ p^{-1}_\theta(u) \cap L_\Theta \subset \bigcup_{i=1}^n C(v_i, \varepsilon_{v_i}). \]
Take an open cone \( C \subset a_\theta \) containing \( u \) such that
\[ p^{-1}_\theta(u) \cap L_\Theta \subset p^{-1}_\theta(C) \cap L_\Theta \subset \bigcup_{i=1}^n C(v_i, \varepsilon_{v_i}). \]
This is indeed possible; if not, there is a sequence of unit vectors \( u_j \in a_\theta \) converging to \( u \) as \( j \to \infty \) such that for each \( j \), there exists \( w_j \in p^{-1}_\theta(u_j) \cap L_\Theta \) that does not belong to \( \bigcup_{i=1}^n C(v_i, \varepsilon_{v_i}) \). Since \( p_\theta | L_\Theta \) is proper and the unit sphere in \( a_\theta \) is compact, we may assume that the sequence \( w_j \) converges to
some \( w \in \mathcal{L}_\Theta \) after passing to a subsequence. Since \( p_\theta(w_j) = u_j \to u \) as \( j \to \infty \), we have \( p_\theta(w) = u \), and hence \( w \in p_\theta^{-1}(u) \cap \mathcal{L}_\Theta \). It implies that \( w_j \in \bigcup_{i=1}^n \mathcal{C}(v_i, \varepsilon_{v_i}) \) for all large \( j \), contradiction.

Since \( \mu_\Theta(\Gamma) \) is within a bounded distance from \( \mathcal{L}_\Theta \) (Lemma 3.4), there are only finitely many elements of \( \mu_\Theta(\Gamma) \) outside of \( \bigcup_{i=1}^n \mathcal{C}(v_i, \varepsilon_{v_i}) \). Hence for each \( s \geq 0 \), we have

\[
\sum_{\gamma \in \Gamma, \mu_\Theta(\gamma) \in \mathcal{C}} e^{-s\|\mu_\Theta(\gamma)\|} \leq \sum_{i=1}^n \sum_{\gamma \in \Gamma, \mu_\Theta(\gamma) \in \mathcal{C}(v_i, \varepsilon_{v_i})} e^{-s\|\mu_\Theta(\gamma)\|} \leq \sum_{i=1}^n \sum_{\gamma \in \Gamma, \mu_\Theta(\gamma) \in \mathcal{C}(v_i, \varepsilon_{v_i})} e^{-s(1-\varepsilon_{v_i}) \|\mu_\Theta(\gamma)\|_{v_{v_i}}}.
\]

Here and afterwards, the notation \( f(s) \ll g(s) \) means that for some uniform constant \( C \geq 1 \), \( f(s) \leq C g(s) \) for all \( s \) at hand. Since \( \tau_\Theta^\theta \geq \psi_\Gamma^\theta(u) > 0 \) is positive, it follows that

\[
\tau_\Theta^\theta \leq \max_i \frac{1}{1-\varepsilon_{v_i}} \|v_i\| \tau_\Theta^\theta(v_i, \varepsilon_{v_i}).
\]

Therefore, together with \( 0 < \varepsilon_{v_i} < \varepsilon \) and (3.10), we get

\[
\psi_\Gamma^\theta(u) \leq \tau_\Theta^\theta \leq \frac{1}{1-\varepsilon} \left( \max_i \psi_\Gamma^\theta(v_i) + \varepsilon \right) \leq \frac{1}{1-\varepsilon} \left( \max_{v \in p_\theta^{-1}(u)} \psi_\Gamma^\theta(v) + \varepsilon \right).
\]

Since \( 0 < \varepsilon < 1 \) was arbitrary, this proves the claim by Lemma 3.12. \( \square \)

**Example 3.14.** We discuss some explicit upper bounds for \( \psi_\Gamma^\theta \) when \( G = \text{PSL}_d(\mathbb{R}) \). Identify \( a^+ = \{(t_1, ..., t_d) : t_1 \geq \cdots \geq t_d, t_1 + \cdots + t_d = 0 \} \). Let \( \alpha_i(t_1, ..., t_d) = t_i - t_{i+1} \) for \( i = 1, 2, ..., d - 1 \). Let

\[
w_i = \left( \frac{d-i}{d}, ..., \frac{d-i}{d}, -\frac{i}{d}, ..., -\frac{i}{d} \right),
\]

where the first \( i \) coordinates are \( \frac{d-i}{d} \)'s and the last \( d-i \) coordinates are \( -\frac{i}{d} \)'s, so that \( a_{\alpha_i} = \mathbb{R}w_i \) and \( \alpha_i(w_i) = 1 \). We compute that

\[
p_{\alpha_i}(t_1, ..., t_d) = \frac{d(t_1 + \cdots + t_i)}{i(d-i)} w_i
\]

and hence

\[
p_{\alpha_i}^{-1}(w_i) \cap a^+ = \{(t_1, ..., t_d) \in a^+ : d(t_1 + \cdots + t_i) = i(d-i) \}.
\]

For any non-lattice discrete subgroup \( \Gamma < \text{PSL}_d(\mathbb{R}) \), we have

\[
\psi_\Gamma(t_1, ..., t_d) \leq \sum_{i<j} (t_i - t_j) - \frac{1}{2} \sum_{i=1}^{\lfloor d/2 \rfloor} (t_i - t_{d+1-i}) \quad (3.11)
\]
by ([36], [29], [27, Theorem 7.1]). By Lemma 3.13 for any discrete non-lattice subgroups, we get
\[
\psi_{\alpha_i}^\Gamma(w_i) \leq \max_{i<j} \sum_{t_i - t_j} - \frac{1}{2} \sum_{i=1}^{[d/2]} (t_i - t_{d+1-i})
\] (3.12)
where the maximum is taken over all \((t_1, \cdots, t_d) \in \mathfrak{a}^+\) such that \(d(t_1 + \cdots + t_i) = i(d - i)\).

For instance, for \(d = 3\), the right hand side is always 3 and hence for each \(i = 1, 2, \psi_{\alpha_i}^\Gamma \leq 3\alpha_i\) on \(Rw_i\).

Hitchin subgroups. Let \(\iota : \text{PSL}_2(\mathbb{R}) \to \text{PSL}_d(\mathbb{R})\) be the irreducible representation, which is unique up to conjugations. A Hitchin subgroup is the image of a representation \(\pi : \Sigma \to \text{PSL}_d(\mathbb{R})\) of a non-elementary geometrically finite subgroup \(\Sigma < \text{PSL}_2(\mathbb{R})\), which belongs to the same connected component as \(\iota|_\Sigma\) in the character variety \(\text{Hom}(\Sigma, \text{PSL}_d(\mathbb{R}))/\sim\) where the equivalence is given by conjugations. Hitchin subgroups are \(\Pi\)-transverse, as defined in the introduction, by [7] and hence \(\alpha_i\)-discrete for each \(i = 1, \cdots, d - 1\). It follows from Lemma 4.5 that if \(\delta_{\alpha_i}\) denotes the abscissa of convergence of \(s \mapsto \sum_{\gamma \in \Gamma} e^{-\alpha_i(\mu(\gamma))}\), then
\[
\psi_{\alpha_i}^\Gamma(w_i) \leq \delta_{\alpha_i} \cdot \alpha_i(w_i) = \delta_{\alpha_i}.
\]
For Hitchin subgroups, it was proved by Potrie and Sambarino [31] for \(\Delta\) cocompact and Canary, Zhang and Zimmer [8] for \(\Delta\) geometrically finite that
\[
\delta_{\alpha_i} \leq 1
\]
for all \(i\) (see also [32]). Hence \(\max_{1 \leq i \leq d-1} \psi_{\alpha_i}(w_i) \leq 1\). We get a sharper bound in the following:

Corollary 3.15. Let \(\Gamma < \text{PSL}_d(\mathbb{R})\) be a Zariski dense Hitchin subgroup. For each \(i = 1, \cdots, d - 1\),
\[
\psi_{\alpha_i}^\Gamma \leq \frac{\max(i, d - i)}{d - 1} \cdot \alpha_i \quad \text{on} \quad \mathfrak{a}_{\alpha_i} - \{0\}.
\]

Proof. For a Zariski dense Hitchin subgroup \(\Gamma < G\), it is shown in [22, Corollary 1.10] that
\[
\psi_{\Gamma}(t_1, \cdots, t_d) < \frac{1}{d - 1} (t_1 - t_d) \quad \text{for} \quad (t_1, \cdots, t_d) \in \mathfrak{a}^+ - \{0\}.
\] (3.13)
Indeed, [22, Corollary 1.10] is stated only for \(\Sigma\) cocompact. However in view of [8] mentioned above, this bound holds for a general Hitchin subgroup. Hence by Lemma 3.13 we get
\[
\psi_{\alpha_i}^\Gamma(w_i) \leq \frac{1}{d - 1} \max (t_1 - t_d)
\] (3.14)
where the maximum is taken over all \(t_1 \geq \cdots \geq t_d\) such that \(d \sum_{j=1}^i t_j = i(d - i)\) and \(\sum_{j=1}^d t_j = 0\). Suppose that this maximum is realized at
(t_1, \cdots, t_d). Since t_1 - t_d does not involve any t_j, 2 \leq j \leq d - 1, we may assume that t_2 = \cdots = t_i and t_{i+1} = \cdots = t_{d-1}, which we denote by \( x \) and \( y \) respectively. Since \( \sum_{j=1}^{i} t_j = \frac{i(i-1)}{d} \) and \( \sum_{j=i+1}^{d} t_j = -\frac{i(d-i)}{d} \), we then have
\[
t_1 = \frac{i(d-i)}{d} - (i-1)x \quad \text{and} \quad t_d = -\frac{i(d-i)}{d} - (d-1-i)y.
\]
Therefore
\[
t_1 - t_d = 2\frac{i(d-i)}{d} - ((i-1)x - (d-1-i)y) \quad (3.15)
\]
where \( \frac{d-i}{d} \geq x \geq y \geq -\frac{i}{d} \). It follows from \( t_j \geq t_{j+1} \) for all \( j \) that \( \frac{d-i}{d} \geq x \geq y \geq -\frac{d}{i} \). Therefore, for each fixed \( x \), the maximum in (3.15) is obtained when \( y = x \). Hence we have
\[
\psi_\Gamma^\alpha(w_i) < \frac{1}{d-1} \max_{x \in [-i/d, (d-i)/d]} \frac{2i(d-i)}{d} - (2i-d)x
\]
\[
= \frac{1}{d-1} \max(i, d-i).
\]
\[\square\]

**Remark 3.16.** We remark that the \( \theta \)-discreteness of \( \Gamma \) does not necessarily imply that the map \( p_\theta|_\mathcal{L} \) is a proper map. For example, let \( \Gamma_0 \) be a Zariski dense convex cocompact subgroup of \( \text{SO}^\circ(k,1) \), \( k \geq 2 \), and let \( \sigma : \Gamma_0 \to \text{SO}^\circ(k,1) \) be a discrete faithful representation such that \( \sigma(\Gamma_0) \) is Zariski dense but not convex cocompact. Consider \( \Gamma = \{(g, \sigma(g)) : g \in \Gamma_0\} \) and \( G = \text{SO}^\circ(k,1) \times \text{SO}^\circ(k,1) \). We may identify \( \mathfrak{a} = \{(x_1, x_2) \in \mathbb{R}^2\} \) and \( \mathfrak{a}^+ = \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \). Then the limit cone of \( \Gamma \) is a convex cone of \( \mathfrak{a}^+ \) containing the \( x_1 \)-axis; otherwise, \( \sigma \) must be convex cocompact. Hence for \( \theta = \{\alpha_2\} \) where \( \alpha_2(x_1, x_2) = x_2 \), \( p_{\theta|_\mathcal{L}}^{-1}(0) \) is the whole \( x_1 \)-axis, and hence \( p_{\theta|_\mathcal{L}} \) is not proper. On the other hand, the discreteness of \( \sigma(\Gamma_0) \) is same as \( \theta \)-discreteness of \( \Gamma \).

4. ON THE PROPER AND CRITICAL LINEAR FORMS

Let \( \Gamma \) be a \( \theta \)-discrete subgroup of \( G \).

**Definition 4.1.** A linear form \( \psi \in \mathfrak{a}_\theta^* \) is called \((\Gamma, \theta)\)-proper if \( \text{Im}(\psi \circ \mu_\theta) \subset [-\epsilon, \infty) \) and \( \psi \circ \mu_\theta : \Gamma \to [-\epsilon, \infty) \) is proper for some \( \epsilon > 0 \).

Consider the series \( \mathcal{P}_\psi = \mathcal{P}_{\Gamma, \psi} \) given by
\[
\mathcal{P}_\psi(s) = \sum_{\gamma \in \Gamma} e^{-s\psi(\mu_\theta(\gamma))}.
\]
(4.1)

The abscissa of convergence of \( \mathcal{P}_\psi \) is well-defined for a \((\Gamma, \theta)\)-proper linear form:

**Lemma 4.2.** If \( \psi \) is \((\Gamma, \theta)\)-proper, the following \( \delta_\psi = \delta_\psi(\Gamma) \) is well-defined and positive (possibly \( +\infty \)):
\[
\delta_\psi := \sup\{s \in \mathbb{R} : \mathcal{P}_\psi(s) = \infty\} = \inf\{s \in \mathbb{R} : \mathcal{P}_\psi(s) < \infty\} \in (0, \infty].
\]
Moreover,
\[ \delta_{\psi} = \limsup_{t \to \infty} \frac{\log \#\{\gamma \in \Gamma : \psi(\mu_{\theta}(\gamma)) \leq t\}}{t}. \]

**Proof.** Since \( \psi \) is \((\Gamma, \theta)\)-proper, \( \psi(\mu_{\theta}(\gamma)) > 0 \) for all but finitely many \( \gamma \in \Gamma \). Hence we may replace \( P_{\psi}(s) \) by the series \( P_{\psi}^+(s) = \sum_{\gamma \in \Gamma, \psi(\mu_{\theta}(\gamma)) > 0} e^{-s\psi(\mu_{\theta}(\gamma))} \) in proving this claim. Since \( P_{\psi}^+(s) \) is a decreasing function of \( s \in \mathbb{R} \), \( I_1 := \{P_{\psi}(s) = \infty\} \) and \( I_2 := \{P_{\psi}(s) < \infty\} \) are disjoing intervals. Since \( \Gamma \) is infinite, \( 0 \in I_1 \), and hence \( \delta_{\psi} = T_1 \cap T_2 \in [0, \infty) \) is well-defined. To show \( \delta_{\psi} > 0 \), fix \( u \in \text{int} L_{\theta} \). Then \( \psi(u) > 0 \) by Lemma 4.3. Since \( \psi_{\Gamma}^0(u) > 0 \) as well by Theorem 3.3(3), we have \( s_0 \psi(u) < \psi_{\Gamma}^0(u) \) for some \( 0 < s_0 < \infty \). By [33] Lemma 3.1.3, we have \( P_{\psi}(s_0) = \infty \), and therefore \( \delta_{\psi} \geq s_0 > 0 \). The last claim follows by [33] Lemma 3.1.1 since the counting measure on \( \psi(\mu_{\theta}(\Gamma)) \) is locally finite and \( \delta_{\psi} > 0 \) as well.

Hence for a \((\Gamma, \theta)\)-proper form \( \psi \in a_\theta^*= \), \( 0 < \delta_{\psi} \leq \infty \) is the abscissa of convergence of \( P_{\psi}(s) \).

**Lemma 4.3.** We have:

1. If \( \psi > 0 \) on \( L_{\theta} - \{0\} \), then \( \psi \) is \((\Gamma, \theta)\)-proper and \( \delta_{\psi} < \infty \).
2. If \( \psi \) is \((\Gamma, \theta)\)-proper, then \( \psi \geq 0 \) on \( L_{\theta} \) and \( \psi > 0 \) on \( \text{int} L_{\theta} \).

**Proof.** If \( \psi \) is positive on \( L_{\theta} - \{0\} \), then \( \psi > 0 \) on some open cone \( C \) containing \( L_{\theta} - \{0\} \). Then for some \( c > 1 \), \( c^{-1} ||u|| \leq \psi(u) \leq c ||u|| \) for all \( u \in C \). Since there can be only finitely many points of \( \mu_{\theta}(\Gamma) \) outside \( C \) by Lemma 3.4, this implies that \( \psi \) is \((\Gamma, \theta)\)-proper. Since \( \delta_{\Gamma}^0 < \infty \) by Proposition 3.7 we also have \( \delta_{\psi} < \infty \).

To prove (2), suppose to the contrary that \( \psi(u) < 0 \) for some \( u \in L_{\theta} \). Then there exists an open cone \( C \subset L_{\theta} \) so that \( \psi < 0 \) on \( C - \{0\} \). In particular, there are infinitely many \( \gamma_i \in \Gamma \) such that \( \psi(\mu_{\theta}(\gamma_i)) < 0 \), which contradicts \((\Gamma, \theta)\)-properness of \( \psi \). Therefore, \( \psi \geq 0 \) on \( L_{\theta} \). Since \( \ker \psi \) is a hyperplane in \( a_\theta^* \), it follows \( \psi > 0 \) on \( \text{int} L_{\theta} \). □

**Critical forms.** Analogous to the critical exponent of a discrete subgroup of a rank one Lie group, we define:

**Definition 4.4.** A linear form \( \psi \in a_\theta^* \) is \((\Gamma, \theta)\)-critical if it is tangent to \( \psi_{\Gamma}^0 \).

The following lemma can be proved by adapting the proof of [22] Theorem 2.5 by replacing \( \psi_{\Gamma}^0 \) by \( \psi_{\Gamma}^0 \).

**Lemma 4.5.** If a \((\Gamma, \theta)\)-proper \( \psi \in a_\theta^* \) satisfies \( \delta_{\psi} < \infty \), then \( \delta_{\psi} \psi \) is \((\Gamma, \theta)\)-critical; in particular,
\[ \psi_{\Gamma}^0 \leq \delta_{\psi} \psi. \]

**Proof.** Suppose that \( \delta_{\psi} < \infty \). By Lemma 4.2 \( \delta_{\psi} > 0 \). We first claim
\[ \psi_{\Gamma}^0(v) \leq \delta_{\psi} \psi(v) \quad \text{for all } v \in \text{int} L_{\theta}. \] (4.3)
Fix \( v \in \text{int} L_{\theta} \) and \( \varepsilon > 0 \). Since \( \psi \) is \((\Gamma, \theta)\)-proper, \( \psi(v) > 0 \) by Lemma 4.3.
We then consider
\[ \mathcal{C}_\varepsilon(v) = \left\{ w \in a_\theta : \psi(w) > 0 \text{ and } \left| \frac{\|w\|}{\psi(w)} - \frac{\|v\|}{\psi(v)} \right| < \varepsilon \right\}; \]
since \( \psi(v) > 0 \), this is a well-defined open cone containing \( v \). Therefore by the definition of \( \psi^0_\Gamma \), we have
\[ \psi^0_\Gamma(v) \leq \|v\| \tau_{\mathcal{C}_\varepsilon(v)}. \] (4.4)

Observe that for any \( s \geq 0 \),
\[ \sum_{\gamma \in \Gamma, \mu_\theta(\gamma) \in \mathcal{C}_\varepsilon(v)} e^{-s\|\mu_\theta(\gamma)||} \leq \sum_{\gamma \in \Gamma, \mu_\theta(\gamma) \in \mathcal{C}_\varepsilon(v)} e^{-s\psi(\mu_\theta(\gamma))}(\frac{\|w\|}{\psi(w)} - \varepsilon) \]
\[ \leq \sum_{\gamma \in \Gamma} e^{-s\psi(\mu_\theta(\gamma))}(\frac{\|w\|}{\psi(w)} - \varepsilon). \]
It follows from the definitions of \( \tau^0_{\mathcal{C}_\varepsilon(v)} \) and \( \delta_\psi \) that
\[ \tau^0_{\mathcal{C}_\varepsilon(v)} \leq \frac{\delta_\psi}{\|v\|\psi(v)^{-1} - \varepsilon} = \frac{\delta_\psi\psi(v)}{\|v\| - \varepsilon\psi(v)}, \]
and hence
\[ \psi^0_\Gamma(v) \leq \frac{\delta_\psi\psi(v)}{\|v\| - \varepsilon\psi(v)}. \]

Since \( \varepsilon > 0 \) is arbitrary, we get \( \psi^0_\Gamma(v) \leq \delta_\psi\psi(v) \), proving the claim (4.3).

We now claim that the inequality (4.3) also holds for any \( v \) in the boundary \( \partial \mathcal{L}_\theta \). Choose any \( v_0 \in \text{int} \mathcal{L}_\theta \). From the concavity of \( \psi^0_\Gamma \) (Theorem 3.3), we have
\[ tv^0_\Gamma(v_0) + (1 - t)\psi^0_\Gamma(v) \leq \psi^0_\Gamma(tv_0 + (1 - t)v) \quad \text{for all } 0 < t < 1. \]
Since \( \mathcal{L}_\theta \) is convex, \( tv_0 + (1 - t)v \in \text{int} \mathcal{L}_\theta \) for all \( 0 < t < 1 \). As we have already shown \( \psi^0_\Gamma \leq \delta_\psi\psi \) on \( \text{int} \mathcal{L}_\theta \), we get
\[ tv^0_\Gamma(v_0) + (1 - t)\psi^0_\Gamma(v) \leq \delta_\psi\psi(tv_0 + (1 - t)v) \quad \text{for all } 0 < t < 1. \]
By sending \( t \to 0^+ \), we get
\[ \psi^0_\Gamma(v) \leq \delta_\psi \cdot \psi(v). \]

Since \( \psi^0_\Gamma = -\infty \) outside \( \mathcal{L}_\theta \), we have established \( \psi^0_\Gamma \leq \delta_\psi\psi \). Suppose that \( \psi^0_\Gamma < \delta_\psi\psi \) on \( a - \{0\} \). Then the abscissa of convergence of the series
\[ s \mapsto \sum_{\gamma \in \Gamma} e^{-s\delta_\psi\psi(\mu_\theta(\gamma))} \]
is strictly less than 1 by Lemma 3.1.3. However the abscissa of convergence of this series is equal to 1 by the definition of \( \delta_\psi \). Therefore \( \delta_\psi\psi \) is tangent to \( \psi^0_\Gamma \), finishing the proof. \( \square \)

**Corollary 4.6.** A \((\Gamma, \theta)\)-proper linear form \( \psi \in a^*_\theta \) with \( \delta_\psi = 1 \) is \((\Gamma, \theta)\)-critical. Moreover, if \( \psi > 0 \) on \( \mathcal{L}_\theta \), then \( \psi \) is \((\Gamma, \theta)\)-critical if and only if \( \delta_\psi = 1 \).

Via the identification \( a^*_\theta = \{ \psi \in a^* : \psi = \psi \circ p_\theta \} \), Lemma 3.13 implies the following identity:
Corollary 4.7. If \( p_\theta |_\mathcal{L} \) is a proper map, then
\[
\{ \psi \in a_\theta^+ : \psi \text{ is } (\Gamma, \theta)-\text{critical} \} = \{ \psi \in a^+: \psi = \psi \circ p_\theta, \psi \text{ is } (\Gamma, \Pi)-\text{critical} \}.
\]

Proof. To show the inclusion \( \supset \), suppose \( \psi = \psi \circ p_\theta \) and \( \psi \) is \((\Gamma, \Pi)\)-critical. Then for any \( u \in a_\theta \) and any \( v' \in p_\theta^{-1}(u) \), \( \psi(u) = \psi(v') \geq \psi_T(v') \) and hence \( \psi(u) \geq \psi_T^\theta(u) \) by Lemma 3.12. Moreover, if \( \psi(v) = \psi_T(v) \), then for \( u = p_\theta(v) \), \( \psi(u) \geq \psi_T^\theta(u) \geq \psi_T(v) = \psi(u) \) and hence \( \psi(u) = \psi_T^\theta(u) \), proving \( \psi \) is \((\Gamma, \theta)\)-critical. For the other inclusion \( \subset \), suppose that \( \psi \geq \psi_T^\theta \) on \( a_\theta^+ \) and \( \psi(u) = \psi_T^\theta(u) \) for some \( u \in a_\theta^+ \). Then for any \( v \in a^+ \), \( \psi(v) = \psi(p_\theta(v)) \geq \psi_T^\theta(p_\theta(v)) \geq \psi_T(v) \) by Lemma 3.12. Let \( v \in p_\theta^{-1}(u) \) be such that \( \psi_T^\theta(u) = \psi_T(v) \) given by Lemma 3.13. Then \( \psi(v) = \psi(u) = \psi_T^\theta(u) = \psi_T(v) \); so \( \psi \) is \((\Gamma, \Pi)\)-critical. \( \square \)

5. LIMIT SET, \( \theta \)-CONICAL SET, AND CONFORMAL MEASURES

Let \( \Gamma \leq G \) be a discrete subgroup.

Definition 5.1 \((\theta\text{-limit set})\). We define the \( \theta \)-limit set of \( \Gamma \) as follows:
\[
\Lambda_\theta = \Lambda_\theta(\Gamma) := \{ \lim \gamma_i \in \mathcal{F}_\theta : \gamma_i \in \Gamma \}
\]
where \( \lim \gamma_i \) is defined as in Definition 2.2.

This is a \( \Gamma \)-invariant closed subset of \( \mathcal{F}_\theta \), which may be empty in general. Set \( \Lambda = \Lambda_{\Pi} \). Denote by \( \text{Leb}_\theta \) the \( K \)-invariant probability measure on \( \mathcal{F}_\theta \).

This definition of \( \Lambda_\theta \) coincides with that of Benoist:

Lemma 5.2 ([3], [34] Corollary 5.2, Lemma 6.3, Theorem 7.2, [28] Lemma 2.13)]. If \( \Gamma \) is Zariski dense in \( G \), we have the following:
1. \( \Lambda_\theta = \{ \xi \in \mathcal{F}_\theta : (\gamma_i)_* \text{Leb}_\theta \to D_\xi \text{ for some infinite sequence } \gamma_i \in \Gamma \} \) where \( D_\xi \) is the Dirac measure at \( \xi \);
2. \( \Lambda_\theta = \pi_\theta(\Lambda) \);
3. \( \Lambda_\theta \) is the unique \( \Gamma \)-minimal subset of \( \mathcal{F}_\theta \).

Definition 5.3 \((\theta\text{-conical set})\). We define the \( \theta \)-conical set of \( \Gamma \) as
\[
\Lambda_\theta^{\text{con}} = \{ g \in \mathcal{F}_\theta : \lim_{\sup} \Gamma gM_\theta A^+ \neq \emptyset \}.
\]

For \( \theta = \Pi \), \( \Lambda_{\Pi}^{\text{con}} = \{ g \in \mathcal{F} : \lim_{\sup} \Gamma gA^+ \neq \emptyset \} \) because \( M_\Pi = M \) commutes with \( \Lambda \). Note that the conical set is not contained in the limit set \( \Lambda \) in general even for \( \theta = \Pi \). For example, if \( G = \text{PSL}_2(\mathbb{R}) \times \text{PSL}_2(\mathbb{R}) \) and \( \Gamma = \Gamma_1 \times \Gamma_2 \) is a product of two convex cocompact subgroups, then \( \Lambda = \Lambda(\Gamma_1) \times \Lambda(\Gamma_2) \) while \( \Lambda^{\text{con}} = (\Lambda(\Gamma_1) \times \mathbb{S}^1) \cup (\mathbb{S}^1 \times \Lambda(\Gamma_2)) \).

\( \theta \)-shadows. For \( q \in X \) and \( R > 0 \), let \( B(q, R) = \{ x \in X : d(x, q) \leq R \} \). For \( p \in X \), the \( \theta \)-shadow \( O^\theta_R(p, q) \subset \mathcal{F}_\theta \) of \( B(q, R) \) viewed from \( p \) is defined as
\[
O^\theta_R(p, q) = \{ g \in \mathcal{F}_\theta : \text{con} \}
\]

where \( g \in \mathcal{F}_\theta \) and \( gM_\theta A^+ \cap B(q, R) \neq \emptyset \).
Lemma 5.4. We have \( \xi \in \Lambda_\theta^\text{con} \) if and only if there exist an infinite sequence \( \gamma_i \in \Gamma \) and \( N > 0 \) such that \( \xi \in \bigcap_i O_N^\theta(o, \gamma_i o) \).

**Proof.** The direction \( \Rightarrow \) is clear. To see the other direction, suppose that \( \xi \in \bigcap_i O_N^\theta(o, \gamma_i o) \) for some \( N > 0 \) and an infinite sequence \( \gamma_i \in \Gamma \), that is, there exist sequences \( k_i \in K \) and \( a_i \to \infty \) in \( A^+ \) such that \( \xi = k_i P_o \) and the sequence \( \gamma_i^{-1} k_i a_i \) is bounded. By passing to a subsequence, we may assume \( k_i \) converges to some \( k \in K \). Since \( \xi = k_i P_o \) for all \( i \), we have \( \xi = k P_o \).

Since \( k_i P_o = k P_o \) and \( M_o = P_o \cap K \), we have \( k_i = k m_i \) for some \( m_i \in M_o \). Since \( \gamma_i^{-1} k m_i a_i = \gamma_i^{-1} k_i a_i \) is bounded, we have \( \xi = k P_o \in \Lambda_\theta^\text{con} \). \( \square \)

We remark that we may replace \( o \) by any \( p \in X \) in the above lemma.

For each \( N > 0 \), we set

\[
\Lambda_N^\theta := \left\{ \xi \in F_\theta : \text{there exists } \gamma_i \to \infty \text{ in } \Gamma \text{ such that } \xi \in \bigcap_i O_N^\theta(o, \gamma_i o) \right\}.
\]

By Lemma 5.4, we have

\[
\Lambda_\theta^\text{con} = \bigcup_{N=1}^\infty \Lambda_N^\theta. \tag{5.3}
\]

**Definition 5.5.** For a \( \theta \)-discrete subgroup \( \Gamma \), we say that \( \Gamma \) is \( \theta \)-regular if for any sequence \( \gamma_i \to \infty \) in \( \Gamma \), we have

\[
\min_{\alpha \in \theta} \alpha(\mu(\gamma_i)) \to \infty.
\]

Observe that \( \theta \)-regularity is same as \( \theta \cup i(\theta) \)-regularity by (2.1) and that not every \( \theta \)-discrete subgroup is \( \theta \)-regular.

**Proposition 5.6.** If \( \Gamma \) is \( \theta \)-regular, then

1. \( \Lambda_\theta^\text{con} \subset \Lambda_\theta \);
2. for any compact subset \( Q \subset G \), the union \( \Gamma Q \cup \Lambda_\theta \) is compact; that is, any infinite sequence has a limit.

**Proof.** To show (1), let \( \xi \in \Lambda_\theta^\text{con} \). Then there exist \( g \in G \), a sequence \( \gamma_i \in \Gamma \), \( m_i \in M_\theta \) and \( a_i \in A^+ \) such that \( \xi = g \xi_0 \) and \( d(gm_i a_i o, \gamma_i o) \) is uniformly bounded. Since \( \mu(\gamma_i) - \log a_i \) is uniformly bounded by Lemma 2.1 and \( \min_{\alpha \in \theta} \alpha(\mu(\gamma_i)) \to \infty \) by the \( \theta \)-regularity, we have \( \min_{\alpha \in \theta} \alpha(\log a_i) \to \infty \) as \( i \to \infty \). We may assume that \( m_i \) converges to some \( m \in M_\theta \) by passing to a subsequence. Therefore as \( i \to \infty \), \( gm_i a_i o \to gm o \xi_0 = g \xi_0 \) by Lemma 2.7. This implies that \( \gamma_i o \to g \xi_0 \) by Lemma 2.6. Hence \( \xi \in \Lambda_\theta \). For (2), if \( \gamma_i \in \Gamma \) is an infinite sequence and \( q_i \in Q \), then \( \min_{\alpha \in \theta} \alpha(\mu(\gamma_i q_i)) \to \infty \) by the \( \theta \)-regularity of \( \Gamma \) and Lemma 2.1. Hence the claim is now immediate from Definition 2.2 and Lemma 2.6. \( \square \)
Conformal measures. The $a$-valued Busemann map $\beta : F \times G \times G \to a$ is defined as follows: for $\xi \in F$ and $g, h \in G$, 
$$\beta_\xi(g, h) := \sigma(g^{-1}, \xi) - \sigma(h^{-1}, \xi)$$
where $\sigma(g^{-1}, \xi) \in a$ is the unique element such that we have the Iwasawa decomposition $g^{-1}k \in K\exp(\sigma(g^{-1}, \xi))N$ for any $k \in K$ with $\xi = kP$. We define the $a_\theta$-valued Busemann map $\beta^\theta : F_\theta \times G \times G \to a_\theta$ as follows: for $(\xi, g, h) \in F_\theta \times G \times G$, we set 
$$\beta^\theta_\xi(g, h) := p_\theta(\beta_{\xi_0}(g, h)) \quad \text{for } \xi_0 \in \pi^{-1}_\theta(\xi); \quad \text{(5.4)}$$
this is well-defined independent of the choice of $\xi_0$ [34, Lemma 6.1].

The following was shown for $\theta = \Pi$ in [28, Lemma 5.7] which directly implies the statement for general $\theta$ since $p_\theta$ is norm-decreasing.

Lemma 5.7. There exists $\kappa > 0$ such that for any $g, h \in G$ and $R > 0$, we have 
$$\sup_{\xi \in \pi^{-1}_\theta(\xi)} \|\beta^\theta_\xi(g, h) - \mu_\theta(g^{-1}h)\| \leq \kappa R.$$ 

Following the work of Patterson-Sullivan ([30], [40]) in rank one, Quint [34] has introduced the notion of conformal measures in general.

Definition 5.8 (Conformal measures). For a linear form $\psi \in a_\theta^*$ and a closed subgroup $\Gamma < G$, a Borel probability measure $\nu$ on $F_\theta$ is called a $(\Gamma, \psi)$-conformal measure if 
$$\frac{d\gamma_\theta \nu}{d\nu}(\xi) = e^{\psi(\beta^\theta_\xi(e, \gamma))} \quad \text{for all } \gamma \in \Gamma \text{ and } \xi \in F_\theta.$$  

Proposition 5.9. Suppose that $\Gamma$ is $\theta$-discrete. For any linear form $\psi \in a_\theta^*$ which is tangent to $\psi^\theta_\Gamma$ at an interior direction of $a_\theta^+$, there exists a $(\Gamma, \psi)$-conformal measure supported on $\Lambda_\theta$.

Proof. For $\theta = \Pi$, this was shown by Quint using the concavity of $\psi_\Gamma$ [34, Theorem 8.4]. Now that we established the concavity of the $\theta$-growth indicator $\psi^\theta_\Gamma$ (Proposition 3.9), the same proof works for general $\theta$. \hfill $\square$

As in the Patterson-Sullivan construction, the conformal measure in the above proposition can be obtained as a limit of a sequence of certain weighted counting measures on $\Gamma o$. The assumption that $\psi$ is tangent to $\psi^\theta_\Gamma$ at an interior direction of $a_\theta^+$ is needed to guarantee that the limiting measure is supported on the limit set $\Lambda_\theta$. For a $\theta$-regular subgroup $\Gamma$, the union $\Gamma o \cup \Lambda_\theta$ is a compact space, and hence the assumption that the tangent direction belongs to $\text{int} a_\theta^+$ is unnecessary. The proof below is an easy adaptation of the standard construction of Patterson-Sullivan (see also [23, Section 2], [39, Section 5], [9]).

Proposition 5.10. Suppose that $\Gamma$ is $\theta$-regular. For any $\psi \in a_\theta^*$ such that $\delta_\psi = 1$ and $\sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} = \infty$, there exists a $(\Gamma, \psi)$-conformal measure supported on $\Lambda_\theta$.
Proof. By Proposition 5.6, $\Gamma \cup \Lambda_\theta$ is a compact space. Recall that $P_\phi(s) = \sum_{\gamma \in \Gamma} e^{-s\delta_\phi(\mu_\phi(\gamma))}$. As $\delta_\phi = 1$, $P_\phi(s) < \infty$ for $s > 1$, and hence we may consider the probability measure on $\Gamma \cup \Lambda_\theta$ given by

$$\nu_\phi(s) := \frac{1}{P_\phi(s)} \sum_{\gamma \in \Gamma} e^{-s\delta_\phi(\mu_\phi(\gamma))}. \quad (5.5)$$

Since the space of probability measures on a compact metric space a weak* compact space, by passing to a subsequence, as $s \to 1$, $\nu_\phi(s)$ weakly converges to a probability measure, say $\nu_\phi$, on $\Gamma \cup \Lambda_\theta$. Since $P_\phi(1) = \infty$, $\nu_\phi$ is supported on $\Lambda_\theta$. It is standard to check that $\nu_\phi$ is a $(\Gamma, \psi)$-conformal measure. □

6. Transverse subgroups and multiplicity of $\theta$-shadows

We say that a discrete subgroup $\Gamma < G$ is $\theta$-antipodal if any two distinct points $\xi \neq \eta$ in $\Lambda_{\theta;\ast}(\theta)$ are in general position, i.e.,

$$\xi = gP_{\theta;\ast}(\theta) \quad \text{and} \quad \eta = gwP_{\theta;\ast}(\theta)$$

for some $g \in G$. Recall that a Zariski dense discrete subgroup $\Gamma < G$ is called $\theta$-transverse if $\Gamma$ is both $\theta$-regular and $\theta$-antipodal. Note that for $\theta_1 \subset \theta_2$, $\theta_2$-transverse implies $\theta_1$-transverse.

Remark 6.1. We may try to define $\Gamma$ to be $\theta$-Antipodal if for any $(\xi, \eta) \in \Lambda_\theta \times \Lambda_\theta$ such that $\pi^{-1}_\theta(\xi) \cap \pi^{-1}_\theta(\eta) = \emptyset$, $(\xi, \eta)$ is in general position, i.e., $\xi = gP_\theta$ and $\eta = gwP_\theta$ for some $g \in G$. While the $\theta$-antipodality implies the $\theta$-Antipodality, the converse direction is not true in general; for instance, any lattice of $\text{PSL}_3(\mathbb{R})$ is $\{\alpha_1\}$-Antipodal but not $\{\alpha_1, \alpha_2\}$-Antipodal, i.e., not $\{\alpha_1\}$-antipodal, where $\alpha_1(\text{diag}(u_1, u_2, u_3)) = u_i - u_{i+1}$ for $i = 1, 2$.

The main aim of this section is to prove the following proposition, which is the essential reason why the main results of this paper are proved for $\theta$-transverse subgroups.

Proposition 6.2 (Bounded multiplicity of $\theta$-shadows). Assume that $\Gamma$ is $\theta$-transverse. Let $\phi \in a_\theta$ be a $(\Gamma, \theta)$-proper linear form. Then for any $R, D > 0$, there exists $q = q(\phi, R, D) > 0$ such that for any $T > 0$, the collection of shadows

$$\left\{O_R^{\theta}(\phi, \gamma) \subset F_\theta : T \leq \phi(\mu_\theta(\gamma)) \leq T + D\right\}$$

have multiplicity at most $q$.

The following lemma is a key ingredient of the proof of Proposition 6.2.

Lemma 6.3. Assume that $\Gamma$ is $\theta$-transverse. For any compact subset $Q$ of $G$, there exists $C_0 = C_0(Q) > 0$ such that if $\gamma_1, \gamma_2 \in \Gamma$ are such that $Q \cap \gamma_1Qa^{-1} \cap \gamma_2Qb^{-1}m^{-1} \neq \emptyset$ for some $a, b \in A_1$ and $m \in M_\theta$, then

$$\min\{||\mu_\theta(\gamma_2) - \mu_\theta(\gamma_1) - \mu_\theta(\gamma_1^{-1}\gamma_2)||, ||\mu_\theta(\gamma_1) - \mu_\theta(\gamma_2) - \mu_\theta(\gamma_2^{-1}\gamma_1)||\} \leq C_0.$$

(6.1)
Proof. Since \( \|p_\theta(u)\| \leq \|p_{\theta,i(\theta)}(u)\| \) for all \( u \in a \), it suffices to prove the lemma for \( \theta \cup i(\theta) \) in place of \( \theta \). Therefore we may assume without loss of generality that \( i(\theta) = \theta \) by replacing \( \theta \) with \( \theta \cup i(\theta) \).

We prove by contradiction. Suppose to the contrary that there exist sequences \( q_{0,i}, q_{1,i}, q_{2,i} \in Q, a_i, b_i \in A^+, m_i \in M_\theta \) and \( \gamma_{1,i}, \gamma_{2,i} \in \Gamma \) such that

\[
\begin{align*}
q_{0,i} &= \gamma_{1,i} q_{1,i} a_i^{-1} = \gamma_{2,i} q_{2,i} b_i^{-1} m_i^{-1}; \quad (6.2) \\
\|\mu_\theta(\gamma_{2,i}) - \mu_\theta(\gamma_{1,i}) - \mu_\theta(\gamma_{1,i}^{-1} \gamma_{2,i})\| &\to \infty; \quad (6.3) \\
\|\mu_\theta(\gamma_{1,i}) - \mu_\theta(\gamma_{2,i}) - \mu_\theta(\gamma_{2,i}^{-1} \gamma_{1,i})\| &\to \infty. \quad (6.4)
\end{align*}
\]

By Lemma \[2.1\], it follows that all sequences \( \gamma_{1,i}, \gamma_{2,i}, \gamma_{1,i}^{-1} \gamma_{2,i} \) and \( \gamma_{2,i}^{-1} \gamma_{1,i} \) are unbounded. Without loss of generality, we assume that each of these sequences tends to infinity. By \[6.2\] and Lemma \[2.1\], there exists \( C' = C'(Q) > 1 \) such that

\[
\sup_i \{\|\mu_\theta(\gamma_{1,i}) - \mu_\theta(a_i)\|, \|\mu_\theta(\gamma_{2,i}) - \mu_\theta(b_i)\|\} \leq C' \quad (6.5)
\]

As \( \Gamma \) is \( \theta \)-regular, as \( i \to \infty \),

\[
\min_{a \in \theta} \alpha(\log a_i), \min_{a \in \theta} \alpha(\log b_i) \to \infty.
\]

Note that \( \alpha(\log w_0^{-1} a^{-1} w_0) = \alpha(i(\log a)) = i(\alpha)(\log a) \) for all \( a \in A \) and all \( \alpha \in \Phi \). Since \( \theta \) is symmetric, it follows that

\[
\min_{a \in \theta} \alpha(\log(w_0^{-1} a_i^{-1} w_0)), \min_{a \in \theta} \alpha(\log(w_0^{-1} b_i^{-1} w_0)) \to \infty. \quad (6.6)
\]

Passing to a subsequence, we may assume that \( q_{1,i} \) converges to some \( q_1 \in Q \). We claim that

\[
q_1 w_0 \xi_\theta \in \Lambda_\theta \quad \text{and} \quad q_1 m_1 w_\xi_\theta \in \Lambda_\theta \quad (6.7)
\]

for some \( m_1 \in M_\theta \) and \( w \in N_K(A) \). By Lemma \[5.6\], we may also assume that \( \gamma_{1,i}^{-1} q_{0,i} \) converges to some \( \xi \in \Lambda_\theta \) as \( i \to \infty \). Since \( \gamma_{1,i}^{-1} q_{0,i} = q_{1,i} a_i^{-1} = q_1 w_0 w_0^{-1} a_i^{-1} w_0 \), it follows from Lemma \[2.7\] and \[6.6\] that \( \xi = q_1 w_0 \xi_\theta \).

Therefore

\[
q_1 w_0 \xi_\theta \in \Lambda_\theta.
\]

Since \( A = A_\theta B_\theta \), we may write \( a_i = a_{1,i} a_{2,i} \in A_\theta^+ B_\theta^+ \) and \( b_i = b_{1,i} b_{2,i} \in A_\theta^+ B_\theta^+ \). Using \( S_\theta = M_\theta B_\theta^+ M_\theta \), write

\[
a_{2,i}^{-1} m_i b_{2,i} = m_{1,i} c_i m_{2,i} \in M_\theta B_\theta^+ M_\theta.
\]

Then

\[
\gamma_{1,i}^{-1} \gamma_{2,i} q_{2,i} = q_{1,i} a_{1,i}^{-1} m_i b_i
\]

\[
= q_{1,i}(a_{1,i}^{-1} b_{1,i})(a_{2,i}^{-1} m_i b_{2,i}) = q_{1,i} m_{1,i} (a_{1,i}^{-1} b_{1,i} c_i) m_{2,i}.
\]

By passing to a subsequence, we have \( w \in N_K(A) \) such that for all \( i \geq 1 \),

\[
d_i := w^{-1} a_{1,i}^{-1} b_{1,i} c_i w \in A^+. \quad (6.8)
\]
Then we have the following:

$$\gamma_{1,i}^{-1}\gamma_{2,i}q_{2,i} = q_{1,i}(m_{1,i}w)d_{i}(w^{-1}m_{2,i}) \in q_{1,i}KA^{+}K. \quad (6.9)$$

Since $\gamma_{1,i}^{-1}\gamma_{2,i} \to \infty$, by the $\theta$-regularity of $\Gamma$, we have $\min_{\alpha \in \theta} \alpha(\log d_{i}) \to \infty$. We may assume that $m_{1,i} \to m_{1} \in M_{\theta}$. By Lemma 5.6 and Lemma 2.7, we get

$$\lim_{i \to \infty} \gamma_{1,i}^{-1}\gamma_{2,i}q_{2,i} = q_{1}m_{1}w_{\theta} \in A_{\theta}$$

by passing to a subsequence. Hence the claim (6.7) is proved.

By the $\theta$-antipodal property of $\Gamma$, two distinct points of $A_{\theta}$ must be in general position; hence (6.7) implies that we must have either

$$w_{\theta} = m_{1}w_{\theta} \quad \text{or} \quad m_{1}w_{\theta} \in N_{\theta}^{+}\xi_{\theta}.$$  

First suppose that $(m_{1}w)_{\xi_{\theta}} \in N_{\theta}^{+}\xi_{\theta}$. By Corollary 2.5, this implies that $w \in M_{\theta}$. As $a_{1,i}^{-1}b_{1,i} \in A_{\theta}$, using the commutativity of $M_{\theta}$ and $A_{\theta}$, we get from (6.8) that $d_{i} = (a_{1,i}^{-1}b_{1,i})^{-1}(w_{1}^{-1}c_{i}w)$. Since $d_{i} \in A^{+}$, $a_{1,i}^{-1}b_{1,i} \in A_{\theta}$, and $w^{-1}c_{i}w \in B_{\theta}$, it follows that $a_{1,i}^{-1}b_{1,i} \in A_{\theta}^{+}$. Hence

$$\mu_{\theta}(d_{i}) = \log a_{1,i}^{-1}b_{1,i} = -\log a_{1,i} + \log b_{1,i} = -\mu_{\theta}(a_{i}) + \mu_{\theta}(b_{i}). \quad (6.10)$$

Since $\|\mu_{\theta}(\gamma_{1,i}^{-1}\gamma_{2,i}) - \mu_{\theta}(d_{i})\|$ is uniformly bounded by (6.9) and Lemma 2.1, (6.10) and (6.5) imply that the sequence $\|\mu_{\theta}(\gamma_{1,i}^{-1}\gamma_{2,i}) + \mu_{\theta}(\gamma_{1,i}) - \mu_{\theta}(\gamma_{2,i})\|$ is uniformly bounded. This contradicts (6.3).

Now suppose the other case that $w_{\theta} = m_{1}w_{\theta}$. In this case, we have

$$w_{\theta} = m_{1}^{-1}w_{\theta} = w_{0}(w_{0}^{-1}m_{1}^{-1}w_{0})_{\theta} = w_{0}$$

since $m_{1} \in M_{\theta}$ and $w_{0}^{-1}M_{\theta}w_{0} = M_{\theta}$ by the symmetricity of $\theta$. Hence we have $w \in w_{0}(P_{\theta} \cap K) = w_{0}M_{\theta} = M_{\theta}w_{0}$, and thus $w_{0}^{-1} \in M_{\theta}$. Since $w_{0}^{-1} \in M_{\theta}$, we may write using (6.8) that

$$w_{0}d_{i}^{-1}w_{0}^{-1} = (w_{0}d_{i}^{-1})^{-1}a_{1,i}b_{1,i}^{-1}c_{i}^{-1}(w_{0}^{-1}) = (a_{1,i}b_{1,i}^{-1})((w_{0}^{-1})^{-1}c_{i}^{-1}(w_{0}^{-1})) \in A_{\theta}B_{\theta}$$

Since $d_{i} \in A^{+}$, we have $w_{0}d_{i}^{-1}w_{0}^{-1} \in A^{+}$. It follows that $a_{1,i}b_{1,i}^{-1} \in A_{\theta}^{+}$. Hence we have

$$\mu_{\theta}(d_{i}^{-1}) = p_{\theta}(\log(w_{0}d_{i}^{-1}w_{0}^{-1})) = \log a_{1,i} - \log b_{1,i} = \mu_{\theta}(a_{i}) - \mu_{\theta}(b_{i}). \quad (6.11)$$

Similarly, (6.9) implies that the sequence $\|\mu_{\theta}(\gamma_{2,i}^{-1}\gamma_{1,i}) - \mu_{\theta}(d_{i}^{-1})\|$ is uniformly bounded. Hence it follows from (6.11) and (6.5) that the sequence $\|\mu_{\theta}(\gamma_{2,i}^{-1}\gamma_{1,i}) - \mu_{\theta}(\gamma_{1,i}) + \mu_{\theta}(\gamma_{2,i})\|$ is uniformly bounded, contradicting (6.4). This completes the proof. \hfill \square
Proof of Proposition 6.2 Suppose that there exists $\xi \in \bigcap_{i=1}^{n} O_{P}^{B}(o, \gamma_{i}o)$ and $T \leq \phi(\mu_{\theta}(\gamma_{i})) \leq T + D$ for some distinct $\gamma_{i} \in \Gamma$, $i = 1, \ldots, n$. Setting $Q = K \Lambda_{R} K$, let $C_{0} = C_{0}(Q)$ be as in Lemma 6.3. Set
\[ D' = D'_{\phi}(Q, D) := \|\phi\|C_{0} + D \]
where $\|\phi\|$ is the operator norm of $\phi : a_{\theta} \to \mathbb{R}$. Then the following number
\[ q := \#\{\gamma \in \Gamma : \phi(\mu_{\theta}(\gamma)) \leq D'\} \]
is finite by the $(\Gamma, \theta)$-properness of $\phi$. We claim that
\[ n \leq 2q; \]
this proves the proposition. It suffices to show that
\[ \max_{i} \min\{\phi(\mu_{\theta}(\gamma_{i}^{-1}\gamma_{i})), \phi(\mu_{\theta}(\gamma_{i}^{-1}\gamma_{1}))\} \leq D', \quad (6.12) \]
as this implies that
\[ n = \#\{\gamma_{1}, \ldots, \gamma_{n}\} \leq \#\{\gamma_{1}\gamma_{i}^{-1} : \gamma \in \Gamma, \phi(\mu_{\theta}(\gamma)) \leq D'\} \leq 2q. \]

To prove (6.12), for each $i = 1, \ldots, n$, there exist $k_{i} \in K$ and $a_{i} \in A^{+}$ such that $\xi = k_{i} \xi_{\theta}$ and $d(k_{i}a_{i}o, \gamma_{i}o) < R$. Then $k_{i} = k_{1}m_{i}$ for some $m_{i} \in K \cap P_{\theta} = M_{\theta}$. Hence we have $d(\gamma_{i}^{-1}k_{1}a_{1}o, o) < R$ and $d(\gamma_{1}^{-1}k_{1}m_{i}a_{i}o, o) < R$, which implies
\[ k_{1} \in Q \cap \gamma_{1}Qa_{1}^{-1} \cap \gamma_{i}Qa_{i}^{-1}m_{i}^{-1}. \]

By Lemma 6.3, we have
\[ \|\mu_{\theta}(\gamma_{i}) - \mu_{\theta}(\gamma_{1}) - \mu_{\theta}(\gamma_{1}^{-1}\gamma_{i})\| \leq C_{0}, \quad \|\mu_{\theta}(\gamma_{i}) - \mu_{\theta}(\gamma_{1}) - \mu_{\theta}(\gamma_{1}^{-1}\gamma_{i})\| \leq C_{0}. \]

Suppose first that $\|\mu_{\theta}(\gamma_{i}) - \mu_{\theta}(\gamma_{1}) - \mu_{\theta}(\gamma_{1}^{-1}\gamma_{i})\| \leq C_{0}$. Now we have
\[
\phi(\mu_{\theta}(\gamma_{1}^{-1}\gamma_{i})) = \phi(\mu_{\theta}(\gamma_{1}^{-1}\gamma_{i}) - (\mu_{\theta}(\gamma_{i}) - \mu_{\theta}(\gamma_{1}))) + \phi(\mu_{\theta}(\gamma_{i}) - \mu_{\theta}(\gamma_{1})) \\
\leq \|\phi\|C_{0} + |\phi(\mu_{\theta}(\gamma_{i})) - \phi(\mu_{\theta}(\gamma_{1}))| \\
\leq \|\phi\|C_{0} + D = D'.
\]
where the last inequality follows from $\phi(\mu_{\theta}(\gamma_{1})), \phi(\mu_{\theta}(\gamma_{i})) \in [T, T + D]$. When $\|\mu_{\theta}(\gamma_{1}) - \mu_{\theta}(\gamma_{i}) - \mu_{\theta}(\gamma_{1}^{-1}\gamma_{i})\| \leq C_{0}$, similarly, we have
\[ \phi(\mu_{\theta}(\gamma_{1}^{-1}\gamma_{i})) \leq \|\phi\|C_{0} + D = D'. \]

Therefore (6.12) follows.

7. DIMENSIONS OF CONFORMAL MEASURES AND GROWTH INDICATORS

For a general Zariski dense discrete subgroup $\Gamma < G$, Quint [34, Theorem 8.1] showed that if there exists a $(\Gamma, \psi)$-conformal measure on $F_{\Pi}$ for $\psi \in a^{*}$, then
\[ \psi \geq \psi_{T}. \]
The main aim of this section is to prove the following analogous inequality for $\theta$-transverse subgroups, using Theorem 7.3 whose key ingredient is the control on multiplicity of shadows obtained in Proposition 6.2.
Theorem 7.1. Let \( \Gamma \) be a \( \theta \)-transverse subgroup of \( G \). If there exists a \((\Gamma, \psi)\)-conformal measure \( \nu \) on \( F_\theta \) for a \((\Gamma, \theta)\)-proper \( \psi \in a_\theta^* \), then
\[
\psi \geq \psi^\theta.
\] (7.1)
Moreover if \( \sum_{\gamma \in \Gamma} e^{-\psi(\mu(\gamma))} = \infty \) in addition, then \( \delta_\psi = 1 \) and \( \psi \) is \((\Gamma, \theta)\)-critical.

Lemma 7.2 (\( \theta \)-shadow lemma). Let \( \Gamma < G \) be a discrete subgroup. Let \( \nu \) be a \((\Gamma, \psi)\)-conformal measure on \( F_\theta \) for \( \psi \in a_\theta^* \). Suppose that \( \text{supp} \, \nu \) is not contained in \( F_\theta - \ell N_\theta^+ P_\theta \) for any \( \ell \in K \). Then we have the following:

1. for some \( R = R(\nu) > 0 \), we have \( c := \inf_{\gamma \in \Gamma} \nu(O^\theta_R(\gamma, o)) > 0 \); and
2. for all \( r \geq R \) and for all \( \gamma \in \Gamma \),
\[
ce^{-\|\psi\|kr} e^{-\psi(\mu(\gamma))} \leq \nu(O^\theta_R(o, \gamma o)) \leq e^{\|\psi\|kr} e^{-\psi(\mu(\gamma))}
\] (7.2)
where \( k > 0 \) is a constant given in Lemma 5.7.

In particular, if \( \Gamma \) is Zariski dense, (7.2) holds for any \((\Gamma, \psi)\)-conformal measure \( \nu \).

Moreover, if \( \Gamma \) is a non-elementary \( \theta \)-transverse subgroup (which is not necessarily Zariski dense), then (7.2) holds for any \((\Gamma, \psi)\)-conformal measure \( \nu \) such that \( \text{supp} \, \nu = \Lambda_\theta \).

Proof. This lemma was proved in [28, Lemma 7.8] for \( \theta = \Pi \), and a general case can be proved verbatim, just replacing \( P \) and \( N \) by \( P_\theta \) and \( N_\theta \) respectively and noting that the projection \( p_\theta : a \to a_\theta \) is a Lipschitz map. We provide a proof for completeness. To prove (1), suppose not. Then there exist \( R_i \to \infty \) and \( \gamma_i \in \Gamma \) such that \( \nu(O^\theta_{R_i}(\gamma^{-1}_i, o)) < 1/i \) for all \( i \geq 1 \). We write the Cartan decomposition \( \gamma_i = k_i a_i \ell_i^{-1} \in KA^+K \) and after passing to a subsequence, we may assume that \( k_i \to k' \) and \( \ell_i \to \ell \) as \( i \to \infty \). We claim that \( N_\theta^+ P_\theta \subset \limsup O^\theta_{R_i}(a^{-1}_i, o) \). Let \( a_i h_i = k_i a_i n_i \in KAN \). Since \( a_i h_i \) is bounded and \( a_i h_i^{-1} = k_i (b_i a_i^{-1})^{-1} \) is bounded, it follows that both sequences \( b_i a_i^{-1} \) and \( n_i \) are bounded. Hence for all large \( i \geq 1 \), \( h_i^{-1} b_i^{-1} a_i o \in B(o, R_i) \) and hence \( h P_\theta = h_n^{-1} b_i^{-1} P_\theta \in O^\theta_{R_i}(a^{-1}_i, o) \). Since \( h_i^{-1} b_i^{-1} = a_i^{-1} k_i \), we have \( h P_\theta \in O^\theta_{R_i}(a^{-1}_i, o) \), proving the claim.

Since \( O^\theta_{R_i}(\gamma^{-1}_i, o) = \ell_{R_i}(a^{-1}_i, o) \) and \( \ell_i \to \ell \), it follows that \( \nu(\ell N_\theta^+ P_\theta) = 0 \). Since \( \ell N_\theta^+ P_\theta \) is Zariski open in \( F_\theta \), it follows that \( \text{supp} \, \nu \cap \ell N_\theta^+ P_\theta = \emptyset \).

This is a contradiction to the hypothesis. Hence this proves (1). To see (2), let \( \gamma \in \Gamma \) and \( r \geq R \). By Lemma 5.7, for all \( \xi \in O^\theta_{r}(\gamma^{-1} o, o) \), we have
\[
\|B^\theta(\gamma^{-1} o, o) - \mu(\theta)\| \leq \kappa r.
\]
Since \( \nu(O^\theta_R(o, o)) = \int_{O^\theta_R(o, o)} e^{\psi(\beta^\theta_R(\gamma^{-1} o, o))} d\nu(\xi) \), (2) follows from (1).

If \( \Gamma \) is Zariski dense, then \( \Lambda \) is Zariski dense in \( F_\theta \) and is contained in \( \text{supp} \, \nu \). Hence any \( \Gamma \)-conformal measure \( \nu \) satisfies the hypothesis.

For the last claim in the statement, let \( \Gamma \) be a non-elementary \( \theta \)-transverse subgroup and \( \nu \) a \((\Gamma, \psi)\)-conformal measure with support \( \Lambda_\theta \), it suffices to show that \( \inf_{\gamma \in \Gamma} \nu(O^\theta_R(\gamma, o)) > 0 \). If not, there exist \( R_i \to \infty \).
and \( \gamma_i \in \Gamma \) such that \( \nu(O_R^\theta(\gamma_i^{-1}a, o)) < 1/i \) for all \( i \geq 1 \). Write the Cartan decomposition \( \gamma_i = k_i'a_i\ell_i^{-1} \in KA^+K \) and assume \( \ell_i \to \ell \in K \) as \( i \to \infty \). By the same argument as above, we have \( \sup \nu \cap \ell N_\theta^P \emptyset = 0 \) and hence \( \Lambda_\theta \cap \ell N_\theta^P \emptyset = \emptyset \). By (2.4), this implies that every element of \( \Lambda_\theta \) is not in general position with \( \ell w_0P_i(\theta) \). On the other hand, it follows from \( \gamma_i^{-1} = \ell_i w_0(w_0^{-1}a_i^{-1}w_0)w_0^{-1}k_i^{-1} \) for all \( i \geq 1 \) that \( \ell w_0P_i(\theta) = \lim_i \gamma_i^{-1} \in \Lambda_i(\theta) \). Since \( \Gamma \) is \( \theta \)-antipodal and \( \#\Lambda_\theta \geq 3 \) by the non-elementary hypothesis on \( \Gamma \), there exists an element of \( \Lambda_\theta \) in general position with \( \ell w_0P_i(\theta) \). This contradicts \( \Lambda_\theta \cap \ell N_\theta^P \emptyset = \emptyset \). This finishes the proof.

**Theorem 7.3.** Let \( \Gamma \) be a Zariski dense \( \theta \)-transverse subgroup of \( G \). If there exists a \((\Gamma, \psi)\)-conformal measure \( \nu \) on \( \mathcal{F}_\theta \) for a \((\Gamma, \theta)\)-proper \( \psi \in a_\theta^* \), then \( \delta \psi \leq 1 \).

**Proof.** For each \( n \in \mathbb{Z} \), we set
\[
\Gamma_{\psi, n} := \{ \gamma \in \Gamma : n \leq \psi(\mu_\theta(\gamma)) < n + 1 \}.
\]
Since \( \psi \) is \((\Gamma, \theta)\)-proper, \( \bigcup_{n<0} \Gamma_{\psi, n} \) is a finite subset, and hence can be ignored in the arguments below. Let \( \nu \) be a \((\Gamma, \psi)\)-conformal measure. We fix a sufficiently large \( R > 0 \) satisfying the conclusion of Lemma 7.2 for \( \nu \).

Since \( \psi \) is a \((\Gamma, \theta)\)-proper linear form, by Proposition 6.2, we have that for all \( n \in \mathbb{N} \),
\[
1 \gg \sum_{\gamma \in \Gamma_{\psi, n}} \nu(O_R^\theta(\gamma o)) \gg \sum_{\gamma \in \Gamma_{\psi, n}} e^{-\psi(\mu_\theta(\gamma))} \geq e^{-(n+1)} \#\Gamma_{\psi, n},
\]
where the implied constants do not depend on \( n \). It implies
\[
\#\Gamma_{\psi, n} \ll e^{n+1} \quad \text{for each } n \geq 0.
\]
Therefore, we have (cf. [33, Lemma 3.1.1])
\[
\delta \psi \leq \limsup_{N \to \infty} \frac{\log \#\{ \gamma \in \Gamma : \psi(\mu_\theta(\gamma)) < N \}}{N} \\
\leq \limsup_{N \to \infty} \frac{1}{N} \log \sum_{0 \leq n < N} e^{n+1} = 1.
\]
(7.3)

Hence the claim follows.

**Proof of Theorem 7.1** By Lemma 4.5 and Theorem 7.3 we have that \( \delta \psi \leq 1 \) and \( \delta \psi \psi \) is tangent to \( \psi_\Gamma^\theta \), and therefore we have
\[
\delta \psi \psi \geq \psi_\Gamma^\theta.
\]
Since \( \psi \) is \((\Gamma, \theta)\)-proper, \( \psi \geq 0 \) on \( \mathcal{L}_\theta \) by Lemma 4.3 and hence \( \psi \geq \delta \psi \psi \) on \( \mathcal{L}_\theta \). Therefore \( \psi \geq \psi_\Gamma^\theta \) on \( \mathcal{L}_\theta \). Since \( \psi_\Gamma^\theta = -\infty \) outside of \( \mathcal{L}_\theta \), \( \psi \geq \psi_\Gamma^\theta \) on \( a_\theta \). If \( \sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} = \infty \) in addition, then \( \delta \psi \geq 1 \) and hence \( \delta \psi = 1 \). In particular, \( \psi = \delta \psi \psi \) is tangent to \( \psi_\Gamma^\theta \). Therefore this finishes the proof.
8. DIVERGENCE OF POINCARÉ SERIES AND CONICAL SETS

Let \( \psi \in a^*_\theta \). Denote by \( M^\theta_\psi = M^\theta_{\Gamma, \psi} \) the collection of all \((\Gamma, \psi)\)-conformal (probability) measures on \( \mathcal{F}_\theta \). We suppose that \( M^\theta_\psi \neq \emptyset \).

The main goal of this section is to prove the following theorem and discuss its applications. Note that we do not assume that \( \psi \) is \((\Gamma, \theta)\)-proper in the following theorem.

**Theorem 8.1.** Let \( \Gamma < G \) be a \( \theta \)-transverse subgroup. If \( \sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} = \infty \) (resp. \( \sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} < \infty \)), then \( \nu(\Lambda^\text{con}_\theta) = 1 \) (resp. \( \nu(\Lambda^\text{con}_\theta) = 0 \)) for all \( \nu \in M^\theta_\psi \).

We make the following simple observation:

**Lemma 8.2.** Suppose that \( \nu(\Lambda^\text{con}_\theta) > 0 \) for all \( \nu \in M^\theta_\psi \). Then \( \nu(\Lambda^\text{con}_\theta) = 1 \) for all \( \nu \in M^\theta_\psi \).

**Proof.** If \( \nu(\Lambda^\text{con}_\theta) < 1 \) for some \( \nu \in M^\theta_\psi \), then \( \nu_F := \frac{1}{\nu(F)} \nu|_F \), for \( F = \mathcal{F}_\theta - \Lambda^\text{con}_\theta \), belongs to \( M^\theta_\psi \) and \( \nu_F(\Lambda^\text{con}_\theta) = 0 \).

We will use the following:

**Lemma 8.3** (Kochen-Stone Lemma [25]). Let \((Z, \nu)\) be a finite measure space. If \( \{A_n\} \) is a sequence of measurable subsets of \( Z \) such that

\[
\sum_{n=1}^{\infty} \nu(A_n) = \infty \quad \text{and} \quad \liminf_{N \to \infty} \frac{\sum_{m=1}^{N} \sum_{n=1}^{N} \nu(A_n \cap A_m)}{\left( \sum_{n=1}^{N} \nu(A_n) \right)^2} < \infty,
\]

(8.1)

then \( \nu(\limsup_n A_n) > 0 \).

**Proof of Theorem 8.1.** Suppose that \( \sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} = \infty \). By Lemma 8.2, it suffices to show that \( \nu(\Lambda^\text{con}_\theta) > 0 \) for all \( \nu \in M^\theta_\psi \). Let \( \nu \in M^\theta_\psi \). We fix \( \alpha \in \theta \). Since \( \Gamma \) is \( \theta \)-regular, \( \alpha \in \theta \) is \((\Gamma, \theta)\)-proper; in particular, \( \alpha(\mu_\theta(\Gamma)) \) is a discrete closed subset of \([0, \infty)\). Therefore we may enumerate \( \Gamma = \{\gamma_1, \gamma_2, \cdots\} \) so that \( \alpha(\mu_\theta(\gamma_n)) \leq \alpha(\mu_\theta(\gamma_{n+1})) \) for all \( n \in \mathbb{N} \). Fix a sufficiently large \( R \) which satisfies the conclusion of Lemma 7.2. Setting \( A_n := O^\theta_R(o, \gamma_n o) \), we then have

\[
\sum_{n=1}^{\infty} \nu(A_n) \geq \sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} = \infty
\]

where the implied constant depends only on \( R \). Since \( \limsup_n A_n \subset \Lambda^\text{con}_\theta \), by Lemma 8.3 it suffices to show that

\[
\liminf_{N \to \infty} \frac{\sum_{m=1}^{N} \sum_{n=1}^{N} \nu(A_n \cap A_m)}{\left( \sum_{n=1}^{N} \nu(A_n) \right)^2} < \infty.
\]

(8.2)
Set $Q := KA_{R}^{+}K$ where $A_{R}^{+} = \{ a \in A^{+} : \|\log a\| \leq R\}$ and $C_{0} = C_{0}(Q)$ be as in Lemma 6.3. Define

$$T_{N} := \max\{ n \in \mathbb{N} : \alpha(\mu_{\theta}(\gamma_{n})) \leq \alpha(\mu_{\theta}(\gamma_{N})) + \|\alpha\|C_{0}\}$$

for each $N \geq 1$. Clearly, $N \leq T_{N}$. Unless mentioned otherwise, all implied constants in this proof are independent of $N$. Since $\Gamma$ is $\theta$-regular, $\alpha|_{\theta}$ is $(\Gamma, \theta)$-proper. Proposition 6.2 implies that the collection $A_{n}$, $N \leq n \leq T_{N}$, has multiplicity at most $q = q(\alpha, R, \|\alpha\|C_{0})$, and hence

$$\sum_{N \leq n \leq T_{N}} \nu(A_{n}) \leq q \cdot \nu(F_{\theta}).$$

Therefore by Lemma 7.2, we have that for all $N \geq 1,

$$\left| \sum_{n=1}^{T_{N}} e^{-\psi(\mu_{\theta}(\gamma_{n}))} - \sum_{n=1}^{N} e^{-\psi(\mu_{\theta}(\gamma_{n}))} \right| \ll \sum_{n=N+1}^{T_{N}} \nu(A_{n})$$

$$\ll \nu(F_{\theta}) = e^{\psi(\mu_{\theta}(\gamma_{1})) - \psi(\mu_{\theta}(\gamma_{1}))} \leq e^{\psi(\mu_{\theta}(\gamma_{1}))} \sum_{n=1}^{N} e^{-\psi(\mu_{\theta}(\gamma_{n}))}$$

with all implied constants independent of $N$. Therefore we have:

$$\sum_{n=1}^{T_{N}} e^{-\psi(\mu_{\theta}(\gamma_{n}))} \ll \sum_{n=1}^{N} e^{-\psi(\mu_{\theta}(\gamma_{n}))}, \quad (8.3)$$

Fix $N \in \mathbb{N}$. If $A_{n} \cap A_{m} \neq \emptyset$ for some $n, m \leq N$, then there exist $k \in K$ and $m_{\theta} \in M_{\theta}$ such that $d(kA^{+}o, \gamma_{n}o) < R$ and $d(km_{\theta}A^{+}o, \gamma_{m}o) < R$. Since $K \subset Q$, it follows that

$$Q \cap \gamma_{n}Qa_{n}^{-1} \cap \gamma_{m}Qa_{m}^{-1}m_{\theta}^{-1} \neq \emptyset$$

for some $a_{n}, a_{m} \in A^{+}$. Hence, setting

$$E_{1} = \{(n, m) : n, m \leq N \text{ and } \|\mu_{\theta}(\gamma_{n}) - (\mu_{\theta}(\gamma_{m}) + \mu_{\theta}(\gamma_{m}^{-1}\gamma_{n}))\| \leq C_{0}\},$$

$$E_{2} = \{(n, m) : n, m \leq N \text{ and } \|\mu_{\theta}(\gamma_{m}) - (\mu_{\theta}(\gamma_{n}) + \mu_{\theta}(\gamma_{n}^{-1}\gamma_{m}))\| \leq C_{0}\},$$

we get from Lemma 6.3 that

$$\sum_{n, m \leq N} \nu(A_{n} \cap A_{m}) \leq \sum_{(n, m) \in E_{1}} \nu(A_{n}) + \sum_{(n, m) \in E_{2}} \nu(A_{m}). \quad (8.4)$$

For all $(n, m) \in E_{1}$, we have

$$\alpha(\mu_{\theta}(\gamma_{m}^{-1}\gamma_{n})) \leq \alpha(\mu_{\theta}(\gamma_{m}) + \mu_{\theta}(\gamma_{m}^{-1}\gamma_{n}))$$

$$= \alpha(\mu_{\theta}(\gamma_{m}) + \mu_{\theta}(\gamma_{m}^{-1}\gamma_{n}) - \mu_{\theta}(\gamma_{n})) + \alpha(\mu_{\theta}(\gamma_{n})) \quad (8.5)$$

$$\leq \|\alpha\|C_{0} + \alpha(\mu_{\theta}(\gamma_{n})).$$
Therefore, by Lemma 7.2,
\[
\sum_{(n,m) \in E_1} \nu(A_n) \ll \sum_{(n,m) \in E_1} e^{-\psi(\mu_\theta(\gamma_n))}
\ll \sum_{(n,m) \in E_1} e^{-\psi(\mu_\theta(\gamma_m))} e^{-\psi(\mu_\theta(\gamma_m^{-1}\gamma_n))}
\leq \sum_{m=1}^N \sum_{j=1}^{T_N} e^{-\psi(\mu_\theta(\gamma_m))} e^{-\psi(\mu_\theta(\gamma_j))};
\]
the last inequality follows because, for each fixed \(1 \leq m \leq N\), the correspondence \(n \leftrightarrow \gamma_m^{-1}\gamma_n\) is one-to-one and when \((n, m) \in E_1\), \(\gamma_j = \gamma_m^{-1}\gamma_n\) for some \(j \leq T_n \leq T_N\) by (8.5). Similarly, we have
\[
\sum_{(n,m) \in E_2} \nu(A_m) \ll \sum_{n=1}^N \sum_{j=1}^{T_N} e^{-\psi(\mu_\theta(\gamma_n))} e^{-\psi(\mu_\theta(\gamma_j))}.
\]
By (8.4), we have
\[
\sum_{n,m \leq N} \nu(A_n \cap A_m) \ll \sum_{n=1}^N \sum_{j=1}^{T_N} e^{-\psi(\mu_\theta(\gamma_n))} e^{-\psi(\mu_\theta(\gamma_j))}
\ll \left( \sum_{n=1}^N e^{-\psi(\mu_\theta(\gamma_n))} \right)^2 \ll \left( \sum_{n=1}^N \nu(A_n) \right)^2
\]
where we have applied (8.3) for the second last inequality and Lemma 7.2 for the last inequality. Hence (8.2) is verified, completing the proof of the first statement.

We now suppose that \(\sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} < \infty\). Consider the following increasing sequence
\[
\Lambda_N^\gamma = \limsup_{\gamma \in \Gamma} O_N^\gamma(o, \gamma o), \quad N \geq 1.
\]
Since \(\Lambda_0^\operatorname{con} = \bigcup_N \Lambda_N^\gamma\), it suffices to show \(\nu(\Lambda_N^\gamma) = 0\) for all sufficiently large \(N \geq 1\). Since
\[
\Lambda_N^\gamma \subset \bigcup_{\gamma \in \Gamma, \|\mu_\theta(\gamma)\| > t} O_N^\gamma(o, \gamma o)
\]
for any \(t > 0\), we get from Lemma 7.2 that for all \(t > 0\),
\[
\nu(\Lambda_N^\gamma) \ll \sum_{\gamma \in \Gamma, \|\mu_\theta(\gamma)\| > t} e^{-\psi(\mu_\theta(\gamma))}
\]
where the implied constant depends only on $N$. Since $\sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} < \infty$ implies that $\lim_{t \to \infty} \sum_{\gamma \in \Gamma, ||\mu_\theta(\gamma)|| > t} e^{-\psi(\mu_\theta(\gamma))}$ = 0, we have $\nu(\Lambda^N_\theta) = 0$, finishing the proof.

**Comparing with $\psi_\Gamma$.** Quint showed that for a discrete subgroup $\Gamma < G$, the existence of a $(\Gamma, \psi)$-conformal measure on $F_\theta$ for $\psi \in a^*_\theta$ implies the inequality

$$\psi \circ p_\theta + 2\rho_{\Pi-\theta} \geq \psi_\Gamma$$

(8.7)

where $2\rho_{\Pi-\theta}$ is the sum of all positive roots which can be written as $\mathbb{Z}$-linear combinations of elements of $\Pi - \theta$ (counted with multiplicity) [34, Theorem 8.1]. For $\theta$-transverse subgroups, Theorem 1.4 and (1.2) imply that the term $2\rho_{\Pi-\theta}$ turns out to be redundant:

**Corollary 8.4.** Let $\Gamma < G$ be a $\theta$-transverse subgroup and $\psi \in a^*_\theta$ be $(\Gamma, \theta)$-proper. If there exists a $(\Gamma, \psi)$-conformal measure $\nu$ on $F_\theta$, then

$$\psi \circ p_\theta \geq \psi_\Gamma$$

(8.8)

Moreover, if $\nu(\Lambda^\text{con}_\theta) > 0$, then $\psi \circ p_\theta$ is tangent to $\psi_\Gamma$.

**Proof.** The first statement follows from Theorem 7.1 and Lemma 3.12. For the second claim, if $\nu(\Lambda^\text{con}_\theta) > 0$, then we have $\sum_{\gamma \in \Gamma} e^{-(\psi \circ p_\theta)(\mu_\theta(\gamma))} = \infty$ by Theorem 8.1. If $\psi \circ p_\theta$ were strictly bigger than $\psi_\Gamma$, then by [33, Lemma 3.1.3] we would have $\sum_{\gamma \in \Gamma} e^{-(\psi \circ p_\theta)(\mu_\theta(\gamma))} < \infty$. Therefore $\psi \circ p_\theta$ must be tangent to $\psi_\Gamma$. \qed

9. Properly discontinuous actions of $\Gamma$

Recall $F^{(2)}_\theta = \{ (\xi, \eta) \in F_\theta \times F_i(\theta) : \xi, \eta \text{ are in general position} \}$ and consider the action of $G$ on the space $F^{(2)}_\theta \times a_\theta$ defined as

$$g.(\xi, \eta, u) = (g\xi, g\eta, u + \beta^\theta(\xi^{-1}, e))$$

(9.1)

for all $g \in G$ and $(\xi, \eta, u) \in F^{(2)}_\theta \times a_\theta$. A discrete subgroup $\Gamma < G$ preserves the subspace $\Lambda^{(2)}_\theta \times a_\theta$ where

$$\Lambda^{(2)}_\theta = (\Lambda_\theta \times \Lambda_i(\theta)) \cap F^{(2)}_\theta.$$

When $\theta = \Pi$, the Hopf parametrization of $G/M$ gives a $G$-equivariant homeomorphism between $F^{(2)} \times a$ and $G/M$, and hence any discrete subgroup $\Gamma < G$ acts properly discontinuously on $F^{(2)} \times a$ and hence the quotient space $\Gamma \backslash \Lambda^{(2)}_\Pi \times a$ is a locally compact Hausdorff space. For a general $\theta$, this is not the case. The aim of this section is to establish the following two theorems on properly discontinuous actions of $\theta$-transverse subgroups.

**Theorem 9.1.** If $\Gamma$ is $\theta$-transverse, the $\Gamma$-action on $\Lambda^{(2)}_\theta \times a_\theta$ is properly discontinuous and hence

$$\Omega_\theta := \Gamma \backslash \Lambda^{(2)}_\theta \times a_\theta$$

is a locally compact Hausdorff space.
For a $(\Gamma, \theta)$-proper form $\phi \in a^*_\theta$, consider the $\Gamma$-action
\begin{equation}
\gamma.(\xi, \eta, s) = (\gamma \xi, \gamma \eta, s + \phi(\beta^\theta_\xi(\gamma^{-1}, e)))
\end{equation}
for all $\gamma \in \Gamma$ and $(\xi, \eta, s) \in \Lambda^{(2)}_\theta \times \mathbb{R}$.

**Theorem 9.2.** Let $\Gamma$ be $\theta$-transverse and $\phi \in a^*_\theta$ a $(\Gamma, \theta)$-proper form. Then the action $\Gamma$ on $\Lambda^{(2)}_\theta \times \mathbb{R}$ given by (9.2) is properly discontinuous and hence $\Omega_\phi := \Gamma \backslash \Lambda^{(2)}_\theta \times \mathbb{R}$ is a locally compact Hausdorff space.

**Definition 9.3.** Let $Z$ be a compact metrizable space with at least 3 points. An action of a countable group $\Gamma$ on $Z$ by homeomorphisms is called a convergence group action if for any sequence of distinct elements $\gamma_n \in \Gamma$, there exist a subsequence $\gamma_{n_k}$ and $a, b \in Z$ such that as $k \to \infty$, $\gamma_{n_k}(z)$ converges to $a$ for all $z \in Z - \{b\}$, uniformly on compact subsets.

We will use the following property of a $\theta$-transverse subgroup:

**Proposition 9.4.** [20] Theorem 4.16] For a $\theta$-transverse subgroup $\Gamma$, the action of $\Gamma$ on $\Lambda_\theta$ is a convergence group action.

The following observation is useful to transfer statements from $\theta$ symmetric to general $\theta$.

**Lemma 9.5.** Suppose that $\Gamma$ is $\theta$-antipodal. For any $\theta_1 \subset \theta_2 \subset \theta \cup i(\theta)$, the projection map $p : \Lambda_{\theta_2} \to \Lambda_{\theta_1}$ given by $gP_{\theta_2} \to gP_{\theta_1}$ is a $\Gamma$-equivariant homeomorphism. In particular, for any $(\Gamma, \psi)$-conformal measure $\nu$ supported on $\Lambda_{\theta_1}$, for $\psi \in a^*_{\theta_1} \subset a^*_{\theta_2}$, the pull back $p^*\nu$ is a $(\Gamma, \psi)$-conformal measure on $\Lambda_{\theta_2}$.

**Proof.** It suffices to show that $p$ is injective when $\theta_2 = \theta \cup i(\theta)$. Suppose that $\xi \neq \eta \in \Lambda_{\theta \cup i(\theta)}$. By the $\theta$-antipodality of $\Gamma$, $\xi = gP_{\theta \cup i(\theta)}$ and $\eta = gw_0P_{\theta \cup i(\theta)}$ for some $g \in G$. Then $p(\xi) = gP_{\theta_1}$ and $p(\eta) = gw_0P_{\theta_1}$, and hence $p(\xi) \neq p(\eta)$, showing that $p$ is injective. \qed

**Lemma 9.6.** There exists $\kappa > 0$ such that for all $r > 0$ and for all $g \in G$,
\[
\sup_{\xi \in O_r(0,g)} \|\beta^\theta_\xi(e, g) - \mu_\theta(g)\| \leq \kappa r.
\]

**Proof.** For $\theta = \Pi$, this follow from [28] Lemma 5.7; let $\kappa$ be the constant for which this lemma is true for $\theta = \Pi$. For $\xi \in O^0_r(o, go)$, choose $\xi' \in O_r(o, go) \subset \mathcal{F}$ such that $\pi_\theta(\xi') = \xi$. Then
\[
\|\beta_{\xi'}(e, g) - \mu(g)\| \leq \kappa r.
\]
Since $\beta^\theta_\xi(e, g) = p_\theta(\beta_{\xi'}(e, g))$, we have
\[
\|\beta^\theta_\xi(e, g) - \mu_\theta(g)\| = \|p_\theta(\beta_{\xi'}(e, g) - \mu(g))\| \leq \|\beta_{\xi'}(e, g) - \mu(g)\| \leq \kappa r.
\]
\qed
Definition 9.7. We say a sequence \( g_i \in G \) converges to \( \xi \in \mathcal{F}_\theta \) conically if \( g_i \to \xi \) in the sense of Definition 2.2 and there exists \( R > 0 \) such that \( \xi \in O_R^\theta(o,g_i o) \) for all \( i \geq 1 \). Note that if \( \gamma_i \in \Gamma \) converges to \( \xi \in \mathcal{F}_\theta \) conically, then \( \xi \in \Lambda_\theta^{\text{con}} \).

The following lemma is stated in [20, Lemma 5.35] in a different language. We give a more direct proof.

Lemma 9.8. Let \( g_i \in G \) be a sequence which converges to \( \xi \in \mathcal{F}_\theta \). Then the following are equivalent:

1. The convergence \( g_i \to \xi \) is conical.
2. For any \( \eta \in \mathcal{F}_{1(\theta)} \) such that \( (\xi, \eta) \in \mathcal{F}_\theta^{(2)} \), the sequence \( g_i^{-1}(\xi, \eta) \) is bounded in \( \mathcal{F}_\theta^{(2)} \).
3. For some \( \eta \in \mathcal{F}_{1(\theta)} \) such that \( (\xi, \eta) \in \mathcal{F}_\theta^{(2)} \), the sequence \( g_i^{-1}(\xi, \eta) \) is bounded in \( \mathcal{F}_\theta^{(2)} \).

Proof. The map \( gL_\theta \to (gP_\theta, gw_\theta P_{1(\theta)}) \) is a \( G \)-equivariant homeomorphism from \( G/L_\theta \) to \( \mathcal{F}_\theta^{(2)} \). We first prove (1) \( \Rightarrow \) (2). Suppose (1). Then there exist sequences \( k_i \in K \) and \( a_i \to \infty \) in \( A^+ \) such that \( \xi = k_i P_\theta \) for all \( i \) and the sequence \( g_i^{-1}k_i a_i \) is bounded. If \( (\xi, \eta) \in \mathcal{F}_\theta^{(2)} \), then \( \xi = hP_\theta \) and \( \eta = hw_\theta P_{1(\theta)} \) for some \( h \in G \). Since \( hP_\theta = k_i P_\theta \), \( h = k_i p_i m_i \) for some \( p_i \in P \) and \( m_i \in M_\theta \), by using \( P_\theta = PM_\theta \). In other words, we have \( k_i^{-1}h m_i^{-1} = p_i \) and hence \( p_i \) is a bounded sequence in \( P \) since \( k_i \) and \( m_i \) are bounded sequences. In particular, it follows from \( a_i \in A^+ \) that the sequence \( a_i^{-1} p_i a_i \) is bounded. Therefore the sequence \( g_i^{-1}h L_\theta = g_i^{-1}k_i p_i L_\theta = (g_i^{-1}k_i a_i)(a_i^{-1} p_i a_i) L_\theta \) is bounded in \( G/L_\theta \), which is equivalent to saying that \( g_i^{-1}(\xi, \eta) \) is bounded, proving (2). The implication (2) \( \Rightarrow \) (3) is clear. Now we prove (3) \( \Rightarrow \) (1). By (3), there exist \( h \in G \) and a sequence \( \ell_i \in L_\theta \) such that \( \xi = h P_\theta \) and \( g_i^{-1} \ell_i \) is a bounded sequence. Since \( L_\theta = M_\theta \Gamma M_\theta \), we can write \( \ell_i = m_i a_i' \ell_i' \in M_\theta \Gamma M_\theta \), and hence we have \( g_i^{-1} h m_i a_i' \) is bounded. For each \( i \), let \( w_i \in K \) be a representative of a Weyl element such that \( w_i^{-1} a_i' w_i \in A^+ \). After passing to a subsequence, we may assume that the sequence \( m_i \) converges to some \( m \in M_\theta \) and \( w_i \) is a constant sequence, say \( w \). We claim that \( w \in M_\theta \). Denoting by \( a_i = w^{-1} a_i' w \in A^+ \),

the sequence \( g_i^{-1} h m_i w a_i \) is bounded. \( (9.3) \)

Moreover, since \( \min_{\alpha \in \Theta} \alpha(\mu(g_i)) \to \infty \), we have \( \min_{\alpha \in \Theta} \alpha(\log a_i) \to \infty \) as \( i \to \infty \) by Lemma 2.1. Since \( g_i \to \xi \), and \( h m_i w a_i = g_i(g_i^{-1} h m_i w a_i) \) and \( g_i^{-1} h m_i w a_i \) is a bounded sequence by \( (9.3) \), we have as \( i \to \infty \), \( \lim h m_i w a_i = \xi \)

by Lemma 2.6. On the other hand, by Lemma 2.7 that as \( i \to \infty \),

\( \lim h m_i w a_i = h w P_\theta \).
Therefore, we have $hmwP_\theta = \xi = hP_\theta$. Since $m \in M_\theta$, it follows that
$$w \in K \cap P_\theta = M_\theta.$$  

In particular, $\xi = hmwP_\theta$ for all $i$.

For each $i$, write $hm_iw = k_ib_i\eta_i \in KAN$ in the Iwasawa decomposition. We then have $\xi = hm_iwP_\theta = k_iP_\theta$. Since the sequence $hm_iw$ is bounded and the product map $K \times A \times N \rightarrow G$ is a diffeomorphism, the sequences $b_i$ and $\eta_i$ are bounded. Since $\eta_i \in A^+$, the sequence $a_i^{-1}n_i\eta_i$ is bounded, and so is the sequence $b_i(a_i^{-1}n_i\eta_i)$. On the other hand, □ implies that
\[
  g_i^{-1}k_ib_in_i\eta_i = (g_i^{-1}k_i)(b_i(a_i^{-1}n_i\eta_i))
\]

Therefore it follows that $g_i^{-1}k_i\eta_i$ is bounded. This means that for some $R > 0$, $\xi = k_iP_\theta \in O_K^0(a, g_i0)$ for all $i$. This proves that $g_i \rightarrow \xi$ conically, as desired.

The following observation will be useful:

**Lemma 9.9.** Let $\Gamma$ be $\theta$-transverse. Let $\gamma_i \in \Gamma$ be an infinite sequence and $(\xi, \eta) \in \Lambda^{(2)}_\theta$. If $\gamma_i(\xi, \eta) \in \Lambda^{(2)}_\theta$ converges in $\Lambda^{(2)}_\theta$, then $\gamma_i^{-1}$ converges conically either to $\xi$ or $\eta$.

**Proof.** We denote by $(\xi_0, \eta_0) \in \Lambda^{(2)}_\theta$ the limit of the sequence $\gamma_i(\xi, \eta)$. Since the projections $\Lambda_{\theta,ij}(g) \rightarrow \Lambda_\theta$ and $\Lambda_{\theta,ij}(g) \rightarrow \Lambda_{0ij}(\theta)$ are homeomorphisms by Lemma 9.5, we also let $\xi_i, \eta_i \in \Lambda_{\theta,ij}(g)$ be the preimages of $\xi$ and $\xi_0$ under the projection $\Lambda_{\theta,ij}(g) \rightarrow \Lambda_\theta$ respectively, and similarly $\eta_i, \eta_0 \in \Lambda_{\theta,ij}(g)$ the preimages of $\eta$ and $\eta_0$. Note that $\xi' \neq \eta'$, $\xi_0 \neq \eta_0$, $\gamma_i\xi' \rightarrow \xi_0$ and $\gamma_i\eta' \rightarrow \eta_0$ as $i \rightarrow \infty$.

Since the action of $\Gamma$ on $\Lambda_{\theta,ij}(g)$ is a convergence group action by Proposition 9.4, there exist $a, b \in \Lambda_{\theta,ij}(g)$ such that
\[
  \gamma_i|_{\Lambda_{\theta,ij}(g)} \rightarrow a
\]
uniformly on compact subsets, after passing to a subsequence. That is, for any compact subsets $C_a \subset \Lambda_{\theta,ij}(g) - \{a\}$ and $C_b \subset \Lambda_{\theta,ij}(g) - \{b\}$,
\[
  \#\{\gamma_i : \gamma_iC_b \cap C_a \neq \emptyset\} < \infty,
\]
or equivalently $\#\{\gamma_i^{-1} : \gamma_i^{-1}C_a \cap C_b \neq \emptyset\} < \infty$. Therefore we have, as $i \rightarrow \infty$,
\[
  \gamma_i^{-1}|_{\Lambda_{\theta,ij}(g)} \rightarrow b
\]
uniformly on compact subsets.

We claim that
\[
  (a, b) = (\eta_0', \xi_0') \quad \text{or} \quad (a, b) = (\xi_0, \eta_0').
\]

Suppose $\xi' \neq b$. Since $\gamma_i\xi' \rightarrow \xi_0'$, □ implies that $\xi_0' = a$. If $\eta'$ were not equal to $b$, then since $\gamma_i\eta' \rightarrow \eta_0'$, □ implies $\eta_0' = a$. Since $\xi_0' \neq \eta_0'$, this is a contradiction. Hence $\eta' = b$. Now suppose that $\xi' = b$. Since $\eta' \neq \xi' = b$, $\gamma_i\eta' \rightarrow a$. Since $\gamma_i\eta'$ is supposed to converge to $\eta_0'$, we have $\eta_0' = a$. This proves the claim.
Now (9.7) and (9.6) imply that
\[ \gamma_i^{-1}|_{\Lambda_{\theta,ij}(\theta)} - \{\eta'\} \to \xi' \quad \text{or} \quad \gamma_i^{-1}|_{\Lambda_{\theta,ij}(\theta)} - \{\xi'\} \to \eta' \] (9.8)
uniformly on compact subsets.

Since $\Gamma$ is $\theta \cup i(\theta)$-regular, we may assume that by passing to a subsequence, the sequence $\gamma_i^{-1}$ converges to some point, say, $z = \lim \gamma_i^{-1}$, in $\Lambda_{\theta,ij}(\theta)$ in the sense of Definition 2.2. We claim that $z$ is either $\xi'$ or $\eta'$. Write $\gamma_i^{-1} = k_ib_i\xi_i^{-1} \in KA^+K$ using the Cartan decomposition. By passing to a subsequence, we may assume that $k_i \to k_0 \in K$ and $\ell_i \to \ell_0 \in K$. Choose $x \in \Lambda_{\theta,ij}(\theta) - \{\eta', \xi'\}$ which is in general position with $\ell_0 w_0 P_{\theta,ij}(\theta)$, which is possible by the Zariski density of $\Gamma$. Since $\Gamma$ is $\theta$-regular, by Lemma 2.4, we have $\min_{\alpha \in \theta} \alpha(\log b_i) \to \infty$. Hence, by Lemma 2.4, we have
\[ \gamma_i^{-1}x \to z = k_0 P_{\theta,ij}(\theta). \]
Therefore, it follows from (9.8) that $z = \xi'$ or $\eta'$. Under the projection $\Lambda_{\theta,ij}(\theta) \to \Lambda_\theta$ and $\Lambda_{\theta,ij}(\theta) \to \Lambda_i(\theta)$, we have
\[ \lim \gamma_i^{-1} = \xi \in \Lambda_\theta \quad \text{or} \quad \lim \gamma_i^{-1} = \eta \in \Lambda_i(\theta). \]

If $\lim \gamma_i^{-1} = \xi \in \Lambda_\theta$, then it follows from $\gamma_i(\xi, \eta) \to (\xi_0, \eta_0)$ in $\Lambda_\theta$ and Lemma 9.8 that the convergence $\gamma_i^{-1} \to \xi$ is conical. Similarly, if $\lim \gamma_i^{-1} = \eta \in \Lambda_i(\theta)$, then the convergence $\gamma_i^{-1} \to \eta$ is conical. It finishes the proof.

**Proposition 9.10.** Let $\Gamma$ be $\theta$-transverse and $\varphi \in a_\theta^\theta$ a $(\Gamma, \theta)$-proper form. Let $\gamma_i \in \Gamma$ be an infinite sequence and $(\xi, \eta) \in \Lambda_\theta^{(2)}$. If $\gamma_i(\xi, \eta) \in \Lambda_\theta^{(2)}$ converges in $\Lambda_\theta^{(2)}$, then the sequence $\varphi(\beta_\xi^\theta(\gamma_i^{-1}, e))$ is unbounded. In particular, $\beta_\xi^\theta(\gamma_i^{-1}, e)$ is unbounded.

**Proof.** Suppose that we have an infinite sequence $\gamma_i \to \infty$ in $\Gamma$ and $(\xi, \eta) \in \Lambda_\theta^{(2)}$ such that $\gamma_i(\xi, \eta)$ converges to $(\xi_0, \eta_0)$ in $\Lambda_\theta^{(2)}$ and
\[ \text{the sequence } \varphi(\beta_\xi^\theta(\gamma_i^{-1}, e)) \text{ is bounded.} \] (9.9)

By Lemma 9.9, we have
\[ \lim \gamma_i^{-1} = \xi \in \Lambda_\theta \quad \text{or} \quad \lim \gamma_i^{-1} = \eta \in \Lambda_i(\theta) \quad \text{conically.} \]

We consider these two cases separately.

**Case A.** Suppose that $\lim \gamma_i^{-1} = \xi$ and the convergence is conical. Then there exists $R > 0$ such that $\xi \in O_R^\theta(o, \gamma_i^{-1}o)$ for all sufficiently big $i$. By Lemma 9.6, we have
\[ \sup_i \|\beta_\xi^\theta(e, \gamma_i^{-1}) - \mu_\theta(\gamma_i^{-1})\| < \infty \]
and hence
\[ \sup_i |\varphi(\beta_\xi^\theta(e, \gamma_i^{-1}) - \mu_\theta(\gamma_i^{-1}))| < \infty. \]
Since $\Gamma$ is $\theta$-regular, we have $\mu_\theta(\gamma_i^{-1}) \to \infty$. Since $\varphi$ is $(\Gamma, \theta)$-proper, we have $\varphi(\mu_\theta(\gamma_i^{-1})) \to \infty$. Therefore

$$\varphi(\beta_\xi^\theta(\gamma_i^{-1}, e)) = -\varphi(\beta_\xi^\theta(e, \gamma_i^{-1})) \to -\infty,$$

contradicting (9.9).

**Case B.** Now suppose that $\gamma_i^{-1} \to \eta$ conically. Choose $g \in G$ so that $\xi = gP_\theta$ and $\eta = gw_0P_{i(\theta)}$. That $\gamma_i^{-1}$ conically converges to $\eta$ means that there exist a sequence $k_i \in K$ and a sequence $a_i \to \infty$ in $A^+$ such that $\eta = k_iP_{i(\theta)}$ for all $i$ and the sequence $\gamma_i k_i a_i$ is bounded. Since $\eta = gw_0P_{i(\theta)} = k_iP_{i(\theta)}$, we have for each $i$, $gw_{i0}P_{i(\theta)} = k_i$ for some $m_i' \in M_{i(\theta)}$ and $p_i \in P$, using $P_{i(\theta)} = M_{i(\theta)}P$. Since both $k_i$ and $m_i'$ are bounded sequences, the sequence $p_i \in P$ is bounded as well. It implies that the sequence $a_i^{-1}p_ia_i$ is bounded since $a_i \in A^+$. Hence it follows from the boundedness of the sequence $\gamma_i k_i a_i = \gamma_i gw_{i0}m_i' p_i a_i = \gamma_i gw_{i0}m_i' (a_i^{-1} p_ia_i)$ that

the sequence $g_i := \gamma_i gw_{i0}m_i' a_i$ is bounded.

For each $i$, set $m_i = w_{i0}m_i' w_0^{-1} \in M_\theta$. Then

$$\eta = gw_0P_{i(\theta)} = gw_{i0}P_{i(\theta)} = gm_iw_0P_{i(\theta)}, \quad \xi = gP_\theta = gm_iP_\theta$$

and

$$g_i = \gamma_i gw_{i0}m_i' a_i = \gamma_i gm_iw_0a_i.$$  

Using $\xi = gm_iP_\theta = gm_i\xi_\theta$, we have

$$\beta_\xi^\theta(\gamma_i^{-1}, e) = \beta_\gamma^\theta(\gamma_i, e_i) = \beta_\gamma^\theta(e, g_i) + \beta_\gamma^\theta(g_i, \gamma_i) = \beta_\gamma^\theta(e, g_i) + \beta_\gamma^\theta(gm_iw_0a_i, e) = \beta_\gamma^\theta(e, g_i) + \beta_\gamma^\theta(w_0a_i, e) + \beta_\gamma^\theta(e, m_i^{-1}g^{-1}).$$

Since $g_i$ is a bounded sequence, the sequence $\beta_\gamma^\theta(e, g_i)$ is bounded by [28, Lemma 5.1]. Similarly, $\beta_\gamma^\theta(e, m_i^{-1}g^{-1})$ is bounded. Hence it suffices to show that as $i \to \infty$,

$$\varphi(\beta_\xi^\theta(w_0a_i, e)) \to \infty. \quad (9.10)$$

Note that

$$\beta_\xi^\theta(w_0a_i, e) = \beta_\xi^\theta(w_0a_iw_0^{-1}, e) = i(\log a_i).$$

Since $g_i = \gamma_i gm_iw_0a_i$ is bounded and $\gamma_i^{-1} g_i = gm_iw_0a_i$, we have $\|\mu(\gamma_i^{-1}) - \log a_i\| = \|\mu(\gamma_i) - i(\log a_i)\|$ is uniformly bounded by Lemma 2.1 and the identity (2.1). Therefore

$$\sup_i |\varphi(\mu(\gamma_i)) - i(\log a_i)| < \infty.$$  

By $\theta$-regularity of $\Gamma$ and the $(\Gamma, \theta)$-properness of $\varphi$, $\varphi(\mu(\gamma_i)) = \varphi(\mu_\theta(\gamma_i)) \to \infty$ and hence $\varphi(i(\log a_i)) \to \infty$, implying (9.10). Hence $\varphi(\beta_\xi^\theta(\gamma_i^{-1}, e)) \to \infty$, yielding the desired contradiction. This finishes the proof. \[\Box\]
Properly discontinuous, there exists an infinite sequence $\gamma \in \Gamma$ and $(\xi, \eta) \in \Lambda^{(2)}_\theta$ such that $\gamma_i(\xi, \eta, u) = (\gamma_i \xi, \gamma_i \eta, u + \beta^\theta(\gamma^{-1}_i, e))$ accumulates in $\Lambda^{(2)} \times a_\theta$. This cannot happen by Proposition 9.10. Hence Theorem 9.1 follows. Theorem 9.2 follows similarly.

Bowen-Margulis-Sullivan measures on $\Omega_\theta$ and $\Omega_\varphi$. We will need the following observations:

Lemma 9.11. If $g, g' \in G$ satisfy $(\xi, \eta) = (gP_\theta, g\varphi_0 P_i(\theta)) = (g'P_\theta, g'\varphi_0 P_i(\theta))$, then

$$\beta^\theta_\xi(e, g) + i(\beta^i_\eta(e, g)) = \beta^\theta_\xi(e, g') + i(\beta^i_\eta(e, g')).$$

Proof. The hypothesis on $g$ and $g'$ means that $g' = gh$ for some $h \in L_\theta$.

Since

$$\beta^\theta_\xi(e, g') + i(\beta^i_\eta(e, g')) = (\beta^\theta_\xi(e, g) + i(\beta^i_\eta(e, g))) + (\beta^\theta_\xi(e, h) + i(\beta^i_\eta(e, h))),$$

it suffices to prove that

$$\beta^\theta_\xi(e, h) + i(\beta^i_\eta(e, h)) = 0.$$

Write $h = as$ where $a \in A_\theta$ and $s \in S_\theta$. Since $p_\theta(A \cap S_\theta) = 0$ and

$$\beta_\xi(e, s) + i(\beta_{w_0 P_i(\theta)}(e, s)) \in A \cap S_\theta,$$

we have

$$\beta^\theta_\xi(e, h) + i(\beta^i_\eta(e, h)) = \beta^\theta_\xi(e, a) + i(\beta^i_\eta P_i(\theta)(e, a)).$$

On the other hand, by the definition of the Busemann map, $\beta_\xi(e, a) = \log a$ and $\beta_{w_0 P}(e, a) = \beta P(e, w_0 a w_0^{-1}) = Ad_{w_0}(\log a) = -i(\log a)$. Hence

$$\beta_\xi(e, a) + i(\beta_{w_0 P}(e, a)) = \log a - i^2(\log a) = 0,$$

finishing the proof.

Lemma 9.12. Let $\Gamma < G$ be a $\theta$-antipodal subgroup and let $\nu$ and $\nu_1$ be measures on $\Lambda_\theta$ and $\Lambda_{i(\theta)}$. If at least one of $\nu$ and $\nu_1$ is atomless, then $\nu \times \nu_1$ is supported on $F^{(2)}_\theta$.

Proof. Replacing $\theta$ by $i(\theta)$ if necessary, we may assume that $\nu_1$ is atomless.

Since $\Gamma$ is $\theta$-antipodal, for each $\xi \in \Lambda_\theta$, there exists at most one $\eta \in \Lambda_{i(\theta)}$ such that $(\xi, \eta) \in F_\theta - F^{(2)}_\theta$. Since $\nu_1$ is atomless, we have

$$(\nu \times \nu_1)(\Lambda_\theta \times \Lambda_{i(\theta)} - F^{(2)}_\theta) = \int_{\Lambda_\theta} \nu_1(\{\eta \in \Lambda_{i(\theta)} : (\xi, \eta) \notin F^{(2)}_\theta\}) \, d\nu(\xi) = 0.$$
Let $\psi \in a_\theta^*$. As $\psi$ can be considered as a linear form on $a$ which is $p_\theta$-invariant and hence $\psi \circ i$ is a linear form on $a$ which is $p_{i(\theta)}$-invariant, we have $\psi \circ i \in a_{i(\theta)}^*$. For a pair of a $(\Gamma, \psi)$-conformal measure $\nu$ on $\Lambda_\theta$ and a $(\Gamma, \psi \circ i)$-conformal measure $\nu_i$ on $\Lambda_{i(\theta)}$, we define a Radon measure $d\tilde{m}_{\nu, \nu}$ on $\Lambda_{(2)} \times a_\theta$ as follows:

$$d\tilde{m}_{\nu, \nu}(\xi, \eta, u) = e^{\psi(B^g(e, g) + i(B^i_{i(\theta)}(e, g)))} d\nu(\xi) d\nu_i(\eta) du$$

(9.11)

where $g \in G$ is chosen so that $(\xi, \eta) = (gP_\theta, gw_0P_{i(\theta)})$ and $du$ is the Lebesgue measure on $a_\theta$. This definition is independent of the choice of $g$ by Lemma 9.11. The measure $d\tilde{m}_{\nu, \nu}$ is left $\Gamma$-invariant and right $A_{\theta}$-invariant. For $\Gamma_{\theta}$-transverse, we denote by $m_{\nu, \nu}$

(9.12)

the $A_{\theta}$-invariant Borel measure on $\Omega_\theta$ induced by $\tilde{m}_{\nu, \nu}$, which we call the Bowen-Margulis-Sullivan measure associated to the pair $(\nu, \nu_i)$.

For a $(\Gamma, \theta)$-proper form $\varphi$, consider the $\Gamma$-equivariant projection $\Lambda_{(2)} \times a_\theta \rightarrow \Lambda_{(2)} \times R$ given by $(\xi, \eta, u) \rightarrow (\xi, \eta, \varphi(u))$. By Theorem 9.2, this induces an affine bundle with fiber ker $\varphi$:

$$\Omega_{(2)} \times a_\theta \rightarrow \Omega_{\varphi};$$

(9.13)

it is a standard fact that such a bundle is indeed a trivial vector bundle and hence we have a homeomorphism

$$\Omega_\theta \simeq \Omega_{\varphi} \times \ker \varphi \simeq \Omega_{\varphi} \times R^{#\theta - 1}.$$  

(9.14)

We denote by the push-forward of the measure $m_{\nu, \nu}$ on $\Omega_\varphi$ by $m_{\nu, \nu}^\varphi$ which is an $R$-invariant Radon measure on $\Omega_{\varphi}$. Then

$$m_{\nu, \nu} = m_{\nu, \nu}^\varphi \otimes \text{Leb}_{\ker \varphi}.$$  

(9.15)

10. Conservativity and ergodicity of the $a_\theta$-action

In this section, we expand the dichotomies in Theorem 8.1 to a criterion on conservativity and ergodicity of $a_\theta$-action on the quotient space $\Omega_{\theta} = \Gamma \backslash \Lambda_{(2)} \times a_\theta$, or equivalently a criterion on conservativity and ergodicity of $R$-action on the quotient space $\Omega_{\varphi} = \Gamma \backslash \Lambda_{(2)} \times R$, when $\Gamma$ is $\theta$-transverse and $\varphi$ is $(\Gamma, \theta)$-proper form. First of all, this makes sense thanks to Theorems 9.1 and 9.2.

We recall the notion of complete conservativity and ergodicity. Let $H$ be a locally compact unimodular group. We denote by $dh$ the Haar measure on $H$. Consider the dynamical system $(H, \Omega, \lambda)$ where $\Omega$ is a separable, locally compact and $\sigma$-compact topological space on which $H$ acts continuously and $\lambda$ is a Radon measure which is quasi-invariant by $H$. A Borel subset $B \subset \Omega$ is called wandering if $\int_H 1_B(h, w) dh < \infty$ for $\mu$-almost all $w \in B$. The Hopf decomposition theorem says that $\Omega$ can be written as the disjoint union $\Omega_C \cup \Omega_D$ of $H$-invariant subsets where $\Omega_D$ is a countable union of wandering subsets which is maximal in the sense that $\Omega_C$ does not contain
any wandering subset of positive measure. If \(\lambda(\Omega_D) = 0\), the system is called completely conservative. If \(\lambda(\Omega_C) = 0\), the system is called completely dissipative. The dynamical system \((H, \Omega, \lambda)\) is ergodic if any \(H\)-invariant \(\lambda\)-measurable subset is either null or co-null. An ergodic system \((H, \Omega, \lambda)\) is either completely conservative or completely dissipative. If \((H, \Omega, \lambda)\) is ergodic, \(H\) is countable and \(\lambda\) is atomless, then it is completely conservative [18, Theorem 14]. The following is standard [27, Lemma 6.1]:

**Lemma 10.1.** Suppose that \(\lambda\) is \(H\)-invariant. Then \((H, \Omega, \lambda)\) is completely conservative if and only if for \(\lambda\)-a.e. \(x \in \Omega\), there exists a compact subset \(B_x \subset \Omega\) such that \(\int_{h \in H} \mathbf{1}_{B_x}(h.x) \, dh = \infty\).

The following theorem implies Theorem 1.9 in the introduction. For \(\psi \in a^*_\theta\), we denote by \(M^0_\psi \subset M^0_{\psi,i}\) the space of all \((\Gamma, \psi)\)-conformal measures supported on \(\Lambda_\theta\).

**Theorem 10.2.** Let \(\Gamma < G\) be a \(\theta\)-transverse subgroup. Let \(\psi \in a^*_\theta\) be \((\Gamma, \theta)\)-proper such that \(M^0_\psi \neq \emptyset\). Then the following are equivalent to each other.

1. \(\sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} = \infty\) (resp. \(\sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} < \infty\));
2. For any \(\nu \in M^0_\psi\), \(\nu(\Lambda^\text{con}_\theta) > 0\) (resp. \(\nu(\Lambda^\text{con}_\theta) = 0\));
3. For any \(\nu \in M^0_\psi\), \(\nu(\Lambda^\text{con}_{\psi,i}) = 1\) (resp. \(\nu(\Lambda^\text{con}_{\psi,i}) = 0\));
4. For any \((\nu, \nu_i) \in M^0_\psi \times M^0_{\psi,i}\), the \(\Gamma\)-action on \((\Lambda^\text{(2)}_\theta, \nu \times \nu_i)\) is completely conservative and ergodic (resp. completely dissipative and non-ergodic);
5. For any \((\nu, \nu_i) \in M^0_\psi \times M^0_{\psi,i}\), the \(a_\theta\)-action on \((\Omega_\theta, m_{\nu,\nu_i})\) is completely conservative and ergodic (resp. completely dissipative and non-ergodic);
6. For any \((\nu, \nu_i) \in M^0_\psi \times M^0_{\psi,i}\) and any \((\Gamma, \theta)\)-proper \(\varphi \in a^*_\theta\), the \(\mathbb{R}\)-action on \((\Omega_\varphi, m^{\varphi,\nu}_{\nu,\nu_i})\) is completely conservative and ergodic (resp. completely dissipative and non-ergodic).

**Proof of Theorem 10.2.** Note that \(a^*_\theta\) can be regarded as a subspace of \(a^*_{\theta,\tilde{i}(\theta)}\) and that \(\psi \in a^*_\theta\) is \((\Gamma, \theta)\)-proper if and only if \(\psi \circ i\) is \((\Gamma, \tilde{i}(\theta))\)-proper. By Lemma 9.5 we have \(\Gamma\)-equivariant homeomorphisms \(\Lambda_\theta \to \Lambda_{\theta,\tilde{i}(\theta)} \to \Lambda_{\tilde{i}(\theta)}\) and hence we can push-forward measures in \(M^0_\psi\) to \(M^0_{\psi,i}\). In particular, \(M^0_{\psi,i} \neq \emptyset\). The equivalence (1) \(\Leftrightarrow\) (2) \(\Leftrightarrow\) (3) follows from Theorem 8.1 and the equivalences (4) \(\Leftrightarrow\) (5) \(\Leftrightarrow\) (6) is immediate from the definition of \(m_{\nu,\nu_i}\) and \(m^{\varphi,\nu}_{\nu,\nu_i}\).

**The first case.** We will show (3) \(\Rightarrow\) (4) \(\Rightarrow\) (1), which will then finish the proof of the first case.
In order to show \((3) \Rightarrow (4)\), assume \((3)\). Consider a pair \((\nu, \nu_i) \in \mathcal{M}_\psi^\theta \times \mathcal{M}_{\psi(\theta)}^{(\theta)}\). We first claim that the \(\Gamma\) action on \((\Lambda_\theta^{(2)}, \nu \times \nu_i)\) is completely conservative. By the hypothesis \((3)\), for \(\nu\)-a.e. \(\xi \in \Lambda_\theta\), \(\xi\) belongs to \(\Lambda_\theta^{\text{con}}\), that is, there exist \(g \in G\) and sequences \(\gamma_i \in \Gamma\), \(m_i \in M_\theta\) and \(a_i \in A^+\) such that \(\xi = gP_\theta\) and the sequence \(h_i := \gamma_i g m_i a_i\) is bounded. Since \(\gamma_i^{-1} = g m_i a_i h_i^{-1}\) and \(\Gamma\) is \(\theta\)-regular, we have \(g m_i a_i \to \xi\) as \(i \to \infty\) by Lemmas \([2.1, 2.7]\) and \([2.6]\) and the boundedness of the sequence \(h_i\), it implies that the sequence \(\gamma_i^{-1}\) converges to \(\xi\). Since \(\gamma_i g m_i a_i\) is bounded, it implies that \(\gamma_i^{-1} \to \xi\) conically. Hence by Lemma \([9.8]\), we have that for any \(\eta \in \Lambda_i(\theta)\) such that \((\xi, \eta) \in \Lambda_\theta^{(2)}\), the sequence \(\gamma_i(\xi, \eta) \in \Lambda_\theta^{(2)}\) is bounded and hence there exists a compact subset \(B(\xi, \eta) \subset \Lambda_\theta^{(2)}\) such that \(\gamma_i(\xi, \eta) \in B(\xi, \eta)\) for all \(i \geq 1\). By Lemma \([10.1]\), this means that the \(\Gamma\) action on \((\Lambda_\theta^{(2)}, \nu \times \nu_i)\) is completely conservative. This implies the ergodicity of the \(\Gamma\)-action on \((\Lambda_\theta^{(2)}, \nu \times \nu_i)\); this was shown in \([24,\text{Lemma 7.6}]\) using an observation due to Blayac-Canary-Zhu-Zimmer \([4]\).

To show the implication \((4) \Rightarrow (1)\), fixing a pair \((\nu, \nu_i) \in \mathcal{M}_\psi^\theta \times \mathcal{M}_{\psi(\theta)}^{(\theta)}\), we will show that the complete conservativity of the \(\Gamma\)-action on \((\Lambda_\theta^{(2)}, \nu \times \nu_i)\) implies \((1)\). Since \((\Gamma, \Lambda_\theta^{(2)}, \nu \times \nu_i)\) is completely conservative, it follows from Lemma \([10.1]\) that for \(\nu \times \nu_i\)-a.e. \((\xi, \eta) \in \Lambda_\theta^{(2)}\), there exists a compact subset \(B(\xi, \eta) \subset \Lambda_\theta^{(2)}\) and a sequence \(\gamma_i \in \Gamma\) such that \(\gamma_i(\xi, \eta) \in B(\xi, \eta)\) for all \(i \geq 1\). In particular, after passing to a subsequence, we have that the sequence \(\gamma_i(\xi, \eta)\) is convergent in \(\Lambda_\theta^{(2)}\). By Lemma \([9.9]\) we have \(\gamma_i^{-1} \to \xi\) or \(\gamma_i^{-1} \to \eta\) conically. In particular, either \(\xi \in \Lambda_\theta^{\text{con}}\) or \(\eta \in \Lambda_i(\theta)\), and therefore

\[
\max\{\nu(\Lambda_\theta^{\text{con}}), \nu_i(\Lambda_i(\theta))\} > 0.
\]

In either case, it follows from Theorem \([8.1]\) that

\[
\sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} = \sum_{\gamma \in \Gamma} e^{-\psi(\mu_{\psi(\theta)}(\mu_{\psi(\theta)}(\gamma)))} = \infty.
\]

Now \((1)\) follows.

**The second case.** From the first case, we have the following equivalences for the second case:

\[(1) \iff (2) \iff (3) \iff (4) \iff (5) \iff (6)\].

We finish the proof by showing \((1) \Rightarrow (4)\). Assume \((1)\) and fix \((\nu, \nu_i) \in \mathcal{M}_\psi^\theta \times \mathcal{M}_{\psi(\theta)}^{(\theta)}\). We first show that the \(\Gamma\) action on \((\Lambda_\theta^{(2)}, \nu \times \nu_i)\) is completely dissipative. We write the Hopf decomposition \(\Lambda_\theta^{(2)} = \Omega_C \cup \Omega_D\) and suppose to the contrary that \(\nu(\nu \times \nu_i)(\Omega_C) > 0\). By applying Lemma \([10.1]\) to the restriction \((\nu \times \nu_i)|_{\Omega_C}\), we deduce that there exists a Borel subset \(\Omega \subset \Lambda_\theta^{(2)}\) with \(\nu(\nu \times \nu_i)(\Omega) > 0\) such that for any \((\xi, \eta) \in \Omega\), there exist a compact subset \(B(\xi, \eta) \subset \Omega\) and a sequence \(\gamma_i \in \Gamma\) such that \(\gamma_i(\xi, \eta) \in B(\xi, \eta)\) for all \(i\).
Hence after passing to a subsequence, the sequence \( \gamma_i(\xi, \eta) \) is convergent in \( \Omega \subset \Lambda_\theta^{(2)} \), and therefore it follows from Lemma 9.9 that \( \gamma_i^{-1} \to \xi \) or \( \gamma_i^{-1} \to \eta \) conically. Since \( (\nu \times \nu_i)(\Omega) > 0 \), it implies
\[
\max\{\nu(\Lambda_\theta^{\text{con}}), \nu_i(\Lambda_i^{\text{con}}(\theta))\} > 0.
\]
In either case, it follows from Theorem 8.1 that
\[
X_{\gamma} \in \Gamma e^{-\psi(\mu(\gamma))} = X_{\gamma} \in \Gamma e^{-\psi_i(\mu_i(\gamma))} = \infty,
\]
which contradicts (1). Therefore, \( (\nu \times \nu_i)(\Omega_C) = 0 \) and hence the \( \Gamma \)-action on \( (\Lambda_\theta^{(2)}, \nu \times \nu_i) \) is completely dissipative.

Now it remains to show that the \( \Gamma \)-action on \( (\Lambda_\theta^{(2)}, \nu \times \nu_i) \) is non-ergodic. Suppose not. Fixing a \((\Gamma, \theta)\)-proper \( \varphi \in a^*_\theta \), we then have that the system \((\mathbb{R}, \Omega_\varphi, m_\varphi)\) is ergodic and completely dissipative. Since any such system for the action \( \mathbb{R} \) is isomorphic to the translation action on \( \mathbb{R} \) with respect to the Lebesgue measure, it follows that \( (\nu \times \nu_i)|_{\Lambda_\theta^{(2)}} \) has an atom, say \((\xi_0, \eta_0)\) \( \in \Lambda_\theta^{(2)} \). By the ergodicity of \((\Gamma, \Lambda_\theta^{(2)}, \nu \times \nu_i)\), \( (\nu \times \nu_i)|_{\Lambda_\theta^{(2)}} \) is supported on the single \( \Gamma \)-orbit \( \Gamma(\xi_0, \eta_0) \). Since \( \nu \) and \( \nu_i \) also have atoms on \( \xi_0 \) and \( \eta_0 \) respectively, we have
\[
(\Gamma \xi_0 \times \Gamma \eta_0) \cap \Lambda_\theta^{(2)} \subset \Gamma(\xi_0, \eta_0).
\]
Since \( \Gamma \) is \( \theta \)-antipodal,
\[
\Gamma \xi_0 \subset \Gamma \eta_0 \xi_0 \cup \{\eta_0\}
\]
where \( \Gamma \eta_0 \) is the stabilizer of \( \eta_0 \) in \( \Gamma \) and \( \eta_0' \) is the image of \( \eta_0 \) under the \( \theta \)-equivariant homeomorphism \( \Lambda_i(\theta) \to \Lambda_\theta \) obtained in Lemma 9.5. In addition, the \( \Gamma \)-equivariance of \( \Lambda_i(\theta) \to \Lambda_\theta \) implies that \( \Gamma \eta_0 = \Gamma \eta_0' \) and hence
\[
\Gamma \xi_0 \subset \Gamma \eta_0' \xi_0 \cup \{\eta_0'\}. \tag{10.1}
\]
Since the \( \Gamma \)-action on \( \Lambda_\theta \) is a convergence group action (Proposition 9.4), \( \Lambda_\theta \) is perfect and equal to the set of all accumulation points of \( \Gamma \xi_0 \). On the other hand, \( \Gamma \eta_0' \) is an elementary subgroup and hence \( \Gamma \eta_0' \xi_0 \) accumulates at most two points in \( \Lambda_\theta \) (\([43, 5]\)). Therefore, we obtain a contradiction and hence the \( \Gamma \)-action on \( (\Lambda_\theta^{(2)}, \nu \times \nu_i) \) is non-ergodic. This proves \((1) \Rightarrow (4)\) in the second case.

Remark 10.3. We remark that our proof of Theorem 10.2 works as long as \( \Gamma \) is non-elementary. The Zariski dense hypothesis was used to apply the shadow lemma (Lemma 7.2) and the \( \Gamma \)-minimality of \( \Lambda_\theta \) (Lemma 7.2). On the other hand, as stated in Lemma 7.2 the shadow lemma also holds for a non-elementary \( \theta \)-transverse subgroup \( \Gamma \) and \( \Gamma \)-conformal measures on \( \Lambda_\theta \). Moreover, the \( \theta \)-limit set of a \( \theta \)-transverse subgroup is same as its limit set as a convergence group acting on the \( \theta \)-limit set (Theorem 4.20) (see also the proof of Lemma 9.9). Hence \( \Gamma \) acts minimally on \( \Lambda_\theta \) by the non-elementary assumption. These observations make all the proofs in this paper work for...
non-elementary \(\theta\)-transverse subgroups and conformal measures on \(\theta\)-limit sets, without the Zariski dense hypothesis.

**Proof of Theorem 1.4.** Theorem 7.1 implies Theorem 1.4(1). Theorem 1.4(2) follows from Theorem 8.1 and the following corollary.

**Corollary 10.4.** Let \(\Gamma\) be \(\theta\)-transverse. If \(\psi \in a_\theta^+\) is \((\Gamma, \theta)\)-proper with \(M_\psi^0 \neq \emptyset\) and \(\sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} = \infty\), then \(#M_\psi^0 = 1\).

**Proof.** By Theorem 7.1 and the hypothesis on \(\psi\), we have \(\delta_\psi = 1\). By Proposition 5.10, for \((\theta\)-transverse subgroup \(\Gamma\), there exists a \((\Gamma, \psi)\)-conformal measure on \(F_{\theta, \psi}(\theta)\), and is supported on \(\Lambda_{\theta, \psi}(\theta)\). Moreover, \(\theta\) is unique by \([9]\). It then follows from Lemma 9.5 that there exists a unique \((\Gamma, \psi)\)-conformal measure on \(F_\theta\) as well. \(\square\)

11. **Lebesgue measures of conical sets and disjoint dimensions**

In this section, we discuss some of consequences of Theorem 8.1.

**Lebesgue measure of conical sets.**

**Theorem 11.1.** If \(\Gamma < G\) is \(\theta\)-transverse, then
\[
\Lambda_\theta = F_\theta \quad \text{or} \quad \text{Leb}(\Lambda_\theta^\text{con}) = 0.
\]
Moreover, in the former case, \(\theta\) is the simple root of a rank one factor of \(G\).

We need the following proposition for the second claim of the above theorem.

**Proposition 11.2.** Suppose that \(\Gamma\) is \(\theta\)-antipodal and that \(\Lambda_\theta = F_\theta\). Then \(\theta\) consists of the simple root of a rank one factor of \(G\).

**Proof.** We write \(G\) as the almost direct product of simple real algebraic groups \(G = G_1 \cdots G_m\). Let \(n\) be an index such that \(\theta\) contains a simple root of \(G_n\). Denoting by \(\pi_n : G \to G_n\) the canonical projection, \(\pi_n(P_\theta)\) is a proper parabolic subgroup of \(G_n\) and the limit set of \(\pi_n(G)\) in \(G_n/\pi_n(P_\theta)\) is equal to all of \(G_n/\pi_n(P_\theta)\). Suppose that the rank of \(G_n\) is at least 2. Fix \(kP_{\theta, \psi}(\theta) \in \Lambda_{\theta, \psi}(\theta)\) for some \(k \in K\). Let \(w\) be a Weyl element given by Lemma 11.3 below such that \(w \notin w_0N_{\theta, \psi}(\theta)P_\theta \cup P_\theta\). Noting that \(w_0N_{\theta, \psi}(\theta)P_{\theta, \psi}(\theta)M_\theta \subset w_0P_\theta^+P_\theta = w_0N_{\theta, \psi}(\theta)P_\theta\), we have
\[
w \notin w_0N_{\theta, \psi}(\theta)P_{\theta, \psi}(\theta)M_\theta \cup P_{\theta, \psi}(\theta). \tag{11.1}\]

Since \(\mathcal{F} = K/M\) and \(kM_\theta \in \mathcal{F}_\theta = K/M_\theta = \Lambda_\theta\), we may choose \(m \in M_\theta\) such that \(kmP \in \Lambda_{\theta, \psi}(\theta)\), and hence \(kwmP_{\theta, \psi}(\theta) \in \Lambda_{\theta, \psi}(\theta)\). Then by (11.1),
\[
wvm \notin w_0N_{\theta, \psi}(\theta)P_{\theta, \psi}(\theta) \cup P_{\theta, \psi}(\theta)\]

The condition that \(wvm \notin P_{\theta, \psi}(\theta)\) implies that \(kwmP_{\theta, \psi}(\theta) \cap kP_{\theta, \psi}(\theta) = \emptyset\). Also, by Corollary 2.5, the condition that \(wvm \notin w_0N_{\theta, \psi}(\theta)P_{\theta, \psi}(\theta)\) implies that \((kwmP_{\theta, \psi}(\theta), kP_{\theta, \psi}(\theta)) \notin G(P_{\theta, \psi}(\theta), w_0P_{\theta, \psi}(\theta))\), that is, \(kwmP_{\theta, \psi}(\theta)\) is
not in general position with \( P_{\theta,\bar{\eta}(\theta)} \). This yields a contradiction to the \( \theta \cup i(\theta) \)-antipodality of \( \Gamma \). Therefore for any \( n \) such that \( \theta \) contains a simple root of \( G_n \), the rank of \( G_n \) must be one. If there are \( n \neq n' \) with this property, the map \( \gamma \to (\pi_n(\gamma), \pi_{n'}(\gamma)) \) must be a discrete subgroup of \( G_nG_{n'} \) (because of the \( \theta \)-regularity property) with full limit set \( G_n/\pi_n(P_{\theta}) \times G_{n'}/\pi_{n'}(P_{\theta}) \). However this yields a contradiction to the \( \theta \)-antipodal property, because the product of two rank one geometric boundaries does not have the antipodal property. Therefore \( \theta \) must be a singleton, proving the claim. \( \square \)

We now prove the following lemma which was used in the above proof.

**Lemma 11.3.** If \( G \) has a connected normal subgroup \( G_n \) of rank at least 2 and \( \theta \in \Pi \) contains a simple root of \( G_n \), then we can find a representative of a Weyl element \( w \in N_K(A) \) such that \( w \notin w_0N_\theta^+P_\theta \cup P_\theta \).

**Proof.** By replacing \( \theta \) with the intersection of \( \theta \) and the set of simple roots of \( G_n \), we may assume without loss of generality that \( G = G_n \). Since the rank of \( G \) is at least 2, we can find a representative \( w \in N_K(A) \) of a Weyl element such that \( \text{Ad}_w(a_\theta^+) \) is equal to neither \( a_\theta^+ \) nor \( -a_\theta^- \). If \( w \) were contained in \( P_\theta \cap K = M_\theta \), \( w \) would commute with \( a_\theta \) and hence \( \text{Ad}_w(a_\theta^+) = a_\theta^+ \).

Therefore \( w \notin P_\theta \). On the other hand, if \( w \in w_0N_\theta^+P_\theta \), then \( w_0^{-1}w \in M_\theta \) by Corollary 2.5, and hence \( \text{Ad}_w(a_\theta^+) = \text{Ad}_{w_0}(a_\theta^+) = -a_\theta^- \), which contradicts our choice of \( w \). Hence \( w \notin w_0N_\theta^+P_\theta \). \( \square \)

**Proof of Theorem 11.1.** Note that \( \text{Leb}_\theta \) is a \( (\Gamma, 2\rho \circ p_\theta) \)-conformal measure where \( \rho \) is the half sum of all positive roots of \( (g, a^+) \) \( \square \). If \( \Lambda_\theta \neq \mathcal{F}_\theta \), \( \text{Leb}_\theta(\Lambda^\text{con}_\theta) \leq \text{Leb}_\theta(\Lambda_\theta) < 1 \) as \( \mathcal{F}_\theta - \Lambda_\theta \) is a non-empty open subset. Therefore \( \text{Leb}_\theta(\Lambda^\text{con}_\theta) = 0 \) by Theorem 8.1. The second claim follows from Proposition 11.2 below. \( \square \)

**Disjoint dimensions and entropy drop.** Recall from the introduction that

\[
\mathcal{D}_\Gamma^\theta = \{ \psi \in a_\theta^+ : (\Gamma, \theta) \text{-proper}, \delta_\psi = 1, \mathcal{P}_\psi(1) = \infty \}.
\]

**Lemma 11.4.** For a \( \theta \)-transverse \( \Gamma \), we have

\[
\mathcal{D}_\Gamma^\theta = \{ \psi \in a_\theta^+ : (\Gamma, \theta) \text{-proper}, \exists a (\Gamma, \psi) \text{-conformal measure}, \mathcal{P}_\psi(1) = \infty \}.
\]

**Proof.** The inclusion \( \subset \) follows from Proposition 5.10. If there exists a \( (\Gamma, \psi) \)-conformal measure on \( \mathcal{F}_\theta \) for \( (\Gamma, \theta) \)-proper \( \psi \), then \( \delta_\psi \leq 1 \) by Theorem 7.3. If \( \delta_\psi < 1 \), \( \mathcal{P}_\psi(1) = \infty \). Hence this implies the inclusion \( \subset \). \( \square \)

Note that any subgroup of a \( \theta \)-transverse subgroup of \( G \) is again a \( \theta \)-transverse subgroup.

**Theorem 11.5** (Disjoint dimensions). Let \( \Gamma < G \) be a \( \theta \)-transverse subgroup. For any Zariski dense subgroup \( \Gamma_0 < \Gamma \) with \( \Lambda_\theta(\Gamma_0) \neq \Lambda_\theta(\Gamma) \), we have

\[
\mathcal{D}_\Gamma^\theta \cap \mathcal{D}_{\Gamma_0}^\theta = \emptyset.
\]
CONFORMAL MEASURES

Proof. Let \( \psi \in \mathcal{D}_0^\theta \). By Proposition 5.10 there exists a \((\Gamma, \psi)\)-conformal measure \( \nu \) on \( \Lambda^\theta(\Gamma) \). By Theorem 1.4, \( \nu(\Lambda^\text{con}_\theta(\Gamma)) = 1 \). While \( \nu \) is also a \((\Gamma_0, \psi)\)-conformal measure, since \( \Lambda^\theta(\Gamma_0) \neq \Lambda^\theta(\Gamma) \) and hence \( \Lambda^\theta(\Gamma) - \Lambda^\theta(\Gamma_0) \) is a non-empty open subset of \( \Lambda^\theta(\Gamma) \), we have \( \nu(\Lambda^\text{con}_\theta(\Gamma_0)) < 1 \). Again by Theorem 1.4, \( \sum_{\gamma \in \Gamma_0} e^{-\psi(\mu(\gamma))} < \infty \). Hence \( \psi \notin \mathcal{D}_{i_0}^\theta \), finishing the proof. \( \square \)

This turns out to be equivalent to the entropy drop phenomenon which is proved by Canary-Zhang-Zimmer [9, Theorem 4.1] for \( \theta = i(\theta) \):

**Corollary 11.6 (Entropy drop).** Let \( \Gamma < G \) be a \( \theta \)-transverse subgroup. Let \( \Gamma_0 < \Gamma \) be a Zariski dense subgroup such that \( \Lambda^\theta(\Gamma_0) \neq \Lambda^\theta(\Gamma) \). If \( \psi \in \mathfrak{a}^*_\theta \) with \( \delta(\psi)(\Gamma) < \infty \) and \( \sum_{\gamma \in \Gamma_0} e^{-\psi(\mu(\gamma))} = \infty \), then

\[
\delta(\psi)(\Gamma_0) < \delta(\psi)(\Gamma).
\]

**Proof.** Suppose that \( \delta(\psi)(\Gamma) < \infty \); this implies that \( \psi \) is \((\Gamma, \theta)\)-proper. Let \( \Gamma_0 < \Gamma \) be as Zariski dense subgroup such that \( \sum_{\gamma \in \Gamma_0} e^{-\delta(\psi)(\Gamma_0)\psi(\mu(\gamma))} = \infty \) and \( \delta(\psi)(\Gamma_0) = \delta(\psi)(\Gamma) \). If we set \( \phi = \delta(\psi)(\Gamma) \cdot \psi = \delta(\psi)(\Gamma_0) \cdot \psi \), then \( \delta(\phi)(\Gamma) = \delta(\phi)(\Gamma_0) = 1 \). Since \( \infty = \sum_{\gamma \in \Gamma_0} e^{-\phi(\mu(\gamma))} \leq \sum_{\gamma \in \Gamma} e^{-\phi(\mu(\gamma))} \), we have \( \phi \in \mathcal{D}_1^\theta \cap \mathcal{D}_2^\theta \). By Theorem 11.5 this implies that \( \Lambda^\theta(\Gamma_0) = \Lambda^\theta(\Gamma) \), proving the corollary. \( \square \)

12. CONFORMAL MEASURES FOR \( \theta \)-ANOSOV SUBGROUPS

Recall the definition of a \( \theta \)-Anosov subgroup given in the introduction. Anosov subgroups are word hyperbolic. The notion of a \( \theta \)-conical set in [20] is equal to the one we use here for \( \theta \)-Anosov subgroups, by the Morse property of \( \theta \)-Anosov subgroups obtained in loc. cit. Note that \( \Gamma \) is \( \theta \)-Anosov if and only if \( \Gamma = \theta \cup i(\theta) \)-Anosov by [2, 1].

**Proposition 12.1 ([16, 20 Theorem 1.1]).** If \( \Gamma \) is \( \theta \)-Anosov, then

1. \( \Gamma \) is \( \theta \)-regular;
2. \( \mathcal{L}_\theta \setminus \{0\} \subset \text{int} \mathfrak{a}^*_\theta ; \)
3. \( \theta \)-antipodal;
4. \( \Lambda^\theta = \Lambda^\text{con}_\theta \).

Therefore a \( \theta \)-Anosov subgroup is \( \theta \)-transverse. We remark that a stronger antipodality is known for \( \theta \)-Anosov subgroups: if \( \Gamma \) is \( \theta \)-Anosov and \( \partial \Gamma \) denotes the Gromov boundary of \( \Gamma \), then there exists a pair of \( \Gamma \)-equivariant homeomorphisms \( f_\theta : \partial \Gamma \to \Lambda^\theta \) and \( f_i(\theta) : \partial \Gamma \to \Lambda^\text{i(\theta)} \) such that if \( \xi \neq \eta \in \partial \Gamma \), then \( f_\theta(\xi) \) and \( f_i(\theta)(\eta) \) are in general position. Our definition of \( \theta \)-antipodality does not require existence of such homeomorphisms.

**Sambarino [39, Theorem A]** showed that if \( \Gamma \) is \( \theta \)-Anosov, then the set \( \{ \psi \in \mathfrak{a}^*_\theta : \delta(\psi) = 1 \} \) is analytic and is equal to the boundary of a strictly convex subset \( \{ \psi \in \mathfrak{a}^*_\theta : 0 < \delta(\psi) < 1 \} \). By the duality lemma ([35, Section 4], [38, Lemma 4.8]), we then deduce the following property of the \( \theta \)-growth indicator:
Theorem 12.2. If $\Gamma$ is $\theta$-Anosov, then $\psi^0_\Gamma$ is strictly concave and vertically tangent.

The vertical tangency means that if $\psi^0_\Gamma(u) = \psi(u)$ for some $(\Gamma, \theta)$-critical form $\psi$ and $u \neq 0$, then $u \in \text{int} \mathcal{L}_\theta$. Recall

$$\mathcal{T}^\theta_\Gamma := \{ \psi \in a^*_\theta : \psi \text{ is } (\Gamma, \theta)\text{-critical} \}.$$ 

Lemma 12.3. If $\Gamma$ is $\theta$-Anosov, then

$$\mathcal{T}^\theta_\Gamma = \{ \psi \in a^*_\theta : (\Gamma, \theta)\text{-proper}, \delta_\psi = 1 \} = \mathcal{D}^\theta_\Gamma.$$

Proof. The second identity is proved in [39, Section 5.9]. It suffices to prove the inclusion $\subset$ in the first equality due to Corollary 4.6. Suppose that $\psi \in a^*_\theta$ is tangent to $\psi^0_\Gamma$. By the vertical tangency property of $\psi^0_\Gamma$ of a $\theta$-Anosov subgroup (Theorem 12.2), $\psi > \psi^0_\Gamma$ on $\partial \mathcal{L}_\theta$. It follows that $\psi > 0$ on $\mathcal{L}_\theta$. Hence by the second claim in Corollary 4.6, $\delta_\psi = 1$. □

Lemma 12.4. If $\Gamma$ is $\theta$-Anosov and there exists a $(\Gamma, \psi)$-conformal measure on $\mathcal{F}_\theta$ for $\psi \in a^*_\theta$, then $\psi$ is $(\Gamma, \theta)$-proper.

Proof. If $\sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} < \infty$, then it implies that $\# \{ \gamma \in \Gamma : \psi(\mu_\theta(\gamma)) < T \}$ is finite for any $T > 0$. Therefore $\psi$ is $(\Gamma, \theta)$-proper. If $\sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} = \infty$, then $\nu(\Lambda_\theta) = 1$ by Theorem 8.1. This implies that $\limsup \frac{1}{T} \log \# \{ \gamma \in \Gamma : \psi(\mu_\theta(\gamma)) < T \} < \infty$ by [39, Theorem A]. Therefore, $\psi$ is $(\Gamma, \theta)$-proper in either case. □

Proof of Theorem 1.12. Let $\Gamma$ be $\theta$-Anosov. Note that a $\theta$-Anosov group is $\theta$-transverse. Hence (1) follows from Theorem 7.1 since $\psi$ is $(\Gamma, \theta)$-proper by Lemma 12.3.

Since $\Lambda_\theta = \Lambda^{\text{con}}_\theta$ (Proposition 12.1), (a) $\Leftrightarrow$ (b) in (2) follows from Theorem 8.1. The equivalence (b) $\Leftrightarrow$ (c) follows from Lemma 12.3 and Sambarino’s parametrization of the space of all conformal measures on $\Lambda_\theta$ as $\{ \delta_\psi = 1 \}$, together with (1) shown above. For (3), let $\psi$ be a $(\Gamma, \theta)$-critical form. By Lemma 12.3 and Proposition 5.10, there exists a $(\Gamma, \psi)$-conformal measure $\nu_\psi$ on $\Lambda_\theta$, which is the unique $(\Gamma, \psi)$-conformal measure on $\Lambda_\theta$ by [39, Theorem A] (see also Corollary 10.4). Since $\sum_{\gamma \in \Gamma} e^{-\psi(\mu_\theta(\gamma))} = \infty$, by Theorem 8.1 any $(\Gamma, \psi)$-conformal measure on $\mathcal{F}_\theta$ is supported on $\Lambda_\theta$. Moreover, by Theorem 10.2 the $a_\theta$-action on $(\Omega_\theta, m_{\nu_\psi, \nu_{\psi_{01}}})$ is completely conservative and ergodic. This finishes the proof.

Proof of Corollary 1.13. Since a $\theta$-Anosov subgroup is $\theta$-transverse and $\Lambda_\theta = \Lambda^{\text{con}}_\theta$ (Proposition 12.1), we deduce from Theorem 11.1 that either $\Lambda_\theta = \mathcal{F}_\theta$ or $\text{Leb}_0(\Lambda_\theta) = 0$. In the former case, $\theta$ is the simple root of a rank one factor $G_0$ of $G$ with $\mathcal{F}_\theta = \Lambda_\theta$ by Proposition 11.2 the projection of $\Gamma$ to $G_0$ is a convex cocompact subgroup with full limit set, and hence a cocompact lattice of $G_0$.

Corollary 1.14 follows from Theorem 1.4 and Lemma 12.3.
Proof of Corollary 1.15. By Theorem 11.5 and Lemma 12.3, it remains to prove the second part. Since $\Gamma_0 < \Gamma$, we have $\psi^0_{\Gamma_0} \leq \psi^0_{\Gamma}$. Suppose that $\psi^0_{\Gamma_0}(u) = \psi^0_{\Gamma}(u)$ for some $u$ in the interior of $L_\theta(\Gamma)$. Then there exists a tangent form $\psi$ to $\psi^0_{\Gamma}$ at $u$ by Corollary 3.11. Since $\psi^0_{\Gamma_0} \leq \psi^0_{\Gamma}$ and $\psi^0_{\Gamma_0}(u) = \psi^0_{\Gamma}(u)$, $\psi$ is also tangent to $\psi^0_{\Gamma_0}$ at $u$. Hence $\psi \in T^0_\theta \cap T^0_{\Gamma_0}$, contradicting the first part.
