1) Tensor-Hom adjunction

Let \( \varphi : A \rightarrow B \) be a homomorphism of commutative rings. By Sec 2 of Lec 19 for a \( B \)-module \( L \) have functors \( L \otimes_A \cdot : A\text{-Mod} \leftrightarrow B\text{-Mod} : \varphi^* \text{Hom}_B(L, \cdot) \).

**Theorem:** \( L \otimes_A \cdot \) is left adjoint of \( \varphi^* \text{Hom}_B(L, \cdot) \).

**Proof:** We write \( L^B \) for \( L \). Let \( M^A, N^B \) be \( A \)- & \( B \)-modules, resp.

We need to produce a bijection

\[ \Psi_{M,N} : \text{Hom}_B(L^B \otimes_A M^A, N^B) \rightarrow \text{Hom}_A(M^A, \text{Hom}_B(L^B, N^B)) \]

which is "natural" (a.k.a. functorial) in \( M^A \) & \( N^B \).

We'll establish "natural" bijections of two sets above

\[ \text{Bilin}_{BA}(L^B \times M^A, N^B) := \{ \beta : L^B \times M^A \rightarrow N^B \} \]

\( B \)-linear in \( L \)-argument, \( A \)-linear in the \( M \)-argument.

**Bijection** \( \Psi_{M,N} : \text{Hom}_B(L^B \otimes_A M^A, N^B) \rightarrow \text{Bilin}_{BA}(L^B \times M^A, N^B) \)

**We need to show that** \( \beta \) is \( B \)-linear \( \iff \) \( \tilde{\beta} \) is \( B \)-linear.
in the $L$-argument; enough to check on generators $L \otimes m$. Note that:

\[ \beta(b(l \otimes m)) = [\text{defn of } B\text{-action on } L \otimes A M] = \beta((b l) \otimes m) = \beta(b l \otimes m) \]

$\beta$ is $B$-linear $\iff \beta(b(l \otimes m)) = 6 \beta(l \otimes m) \iff \beta(b(l \otimes m)) = \beta(b \otimes l \otimes m) \iff \beta$ is $B$-linear in the 1st argument. So we get the required bijection $\mathcal{E}_{m,n}^1$.

Now need functoriality of $\mathcal{E}_{m,n}^2$ — two commutative diagrams, e.g.

\textbf{Exer.} for $\gamma \in \text{Hom}_A(M^A, M^A)$ we have commutative diagram

\[
\begin{array}{ccc}
\text{Hom}_B(L^B \otimes A M^A, N^B) & \xrightarrow{\mathcal{E}_{m,n}^1} & \text{Bilin}_{B A}(L^B \times M^A, N^B) \\
\downarrow \quad \quad \gamma_*(id_B \otimes \phi) & & \quad \downarrow \quad \gamma_*(id_B \times \phi) \\
\text{Hom}_B(L^B \otimes A M^A, N^B) & \xrightarrow{\mathcal{E}_{m,n}^1} & \text{Bilin}_{B A}(L^B \times M^A, N^B)
\end{array}
\]

Similarly, have commutative diagram for $\psi \in \text{Hom}_B(N^B, N^B)$

\[
\begin{array}{ccc}
\text{Bilin}_{B A}(L^B \times M^A, N^B) & \xrightarrow{\mathcal{E}_{m,n}^2} & \text{Hom}_A(M^A, \text{Hom}_B(L^B, N^B)) \\
\downarrow \quad \quad \beta_*(m \mapsto \beta_m) & & \quad \downarrow \quad \beta_*(m \mapsto \beta_m) \\
\text{Bilin}_{B A}(L^B \times M^A, N^B) & \xrightarrow{\mathcal{E}_{m,n}^2} & \text{Hom}_A(M^A, \text{Hom}_B(L^B, N^B))
\end{array}
\]

Functorial in $M^A$ & $N^B$. \hfill \square

2) Additive functors

2.1) Definition Let $A, B$ be commutative rings so that we can consider their categories of modules $A\text{-Mod}$, $B\text{-Mod}$. $\text{Hom}$ sets
In these categories are abelian groups.

**Definition:** A functor $F: A\text{-Mod} \to B\text{-Mod}$ is additive if for any $A$-modules $M, N$, the map $\hom_A(M, N) \to \hom_B(F(M), F(N))$, $\psi \mapsto F(\psi)$, is a group homomorphism.

Similarly, we can talk about additive functors $A\text{-Mod} \to B\text{-Mod}$.

**2.2) Examples.**

0) Let $\phi: A \to B$ be a homomorphism of commutative rings. The pullback functor $\phi^*: B\text{-Mod} \to A\text{-Mod}$ is additive.

1) Let $S \subseteq A$ be a multiplicative subset. The localization functor $A\text{-Mod} \to A[S^{-1}]\text{-Mod}$ is additive: by Problem 8, pt. 1 in HW3, $\psi \mapsto \psi[S^{-1}]: \hom_A(M, N) \to \hom_{A[S^{-1}]}(M[S^{-1}], N[S^{-1}])$ is $A$-linear, hence additive.

2) In the setting of 0), let $L$ be a $B$-module. The functor $L \otimes_A: A\text{-Mod} \to B\text{-Mod}$ is additive (by exercise in Sec 4.4 in Lec 17, the map $\psi \mapsto \text{id}_L \otimes \psi: \hom_A(M, M') \to \hom_B(L \otimes_A M, L \otimes_A M')$ is additive).

3) For an $A$-module $M$, the functor $\hom_A(M, \cdot): A\text{-Mod} \to A\text{-Mod}$ is additive, see a) of Prob 7 of HW1.

More generally, let $\phi: A \to B$ be a ring homomorphism and $L$ be a $B$-module. Let $N$ be an $A$-module. We equip $\hom_A(L, N)$
Exercise: Check that:

i) This equips $\text{Hom}_A(L,N)$ with a $B$-module structure.

ii) $\text{Hom}_A(L,\ast)$: $A$-Mod $\rightarrow$ $B$-Mod (with the usual map on the level of morphisms) is additive.

3. For an $A$-module $N$, $\text{Hom}_A(\ast,N)$ is an additive functor $A$-$\text{Mod}^{\text{opp}} \rightarrow A$-$\text{Mod}$. More generally, for a $B$-module $L$, $\text{Hom}_A(M,L)$ becomes a $B$-module via $[6\psi](m) = 6(\psi(m))$. This defines an additive functor $A$-$\text{Mod}^{\text{opp}} \rightarrow B$-$\text{Mod}$. Checking the details is left as an exercise.

4) Functor $\cdot \otimes_2$: $A$-$\text{Mod} \rightarrow A$-$\text{Mod}$, $M \otimes_2 = M \otimes A$, $\varphi \otimes_2 = \varphi \otimes \varphi$ is not additive (exercise)

3) Exactness

This is the main property of additive functors we care about in Comm. algebra. It describes how a functor behaves on exact sequences.

3.1) Exact sequences: Let $M_0 \xrightarrow{g_0} M_1 \xrightarrow{g_1} \ldots \xrightarrow{g_{k-1}} M_k$ be sequence of $A$-modules & their homomorphisms $g_i \in \text{Hom}_A(M_i, M_{i+1})$, $i=0,\ldots,k-1$. 

**Definition:** this sequence is exact if $\text{im} g_{i-1} = \ker g_i$, $i=1,\ldots,k-1$.

A short exact sequence (SES) is exact sequence of form:

$\quad$
Example (of SES) if \(N \subseteq M\) is an \(A\)-submodule, then have SES 
\[ 0 \rightarrow N \rightarrow M \rightarrow M/N \rightarrow 0, \]
where the 1st map is the inclusion, and the 2nd map is the projection.

In a way, every SES looks like this: \(g_1\) identifies \(M\) w. submodule of \(M_1\), \(g_2\) identifies \(M\) w. \(M_2/\text{im}g_1\).

3.2) Definition of exactness of functors

Let \(A, B\) be commutative rings, \(F: A\text{-Mod} \rightarrow B\text{-Mod}\) be an additive functor.

Definition (of left & right exact functors):

If \( \forall \text{ SES } 0 \rightarrow M_i \xrightarrow{g_i} M_2 \xrightarrow{g_2} M_3 \rightarrow 0 \)

(i) the sequence \( 0 \rightarrow F(M_1) \xrightarrow{F(g_1)} F(M_2) \xrightarrow{F(g_2)} F(M_3) \) is exact,
then say \(F\) is left exact.

(ii) the sequence \( F(M_1) \rightarrow F(M_2) \rightarrow F(M_3) \rightarrow 0 \) is exact,
then say \(F\) is right exact.

Rem: can define left/right exact functors \(F: A\text{-Mod}^{op} \rightarrow B\text{-Mod}^{op}\) e.g. in (i) require that
\[ 0 \rightarrow F(M_1) \xrightarrow{F(g_1)} F(M_2) \xrightarrow{F(g_2)} F(M_3) \]
is exact.

**Def:** For \( F : \text{A-Mod} \rightarrow \text{B-Mod} \), or \( \text{A-Mod}^{\text{opp}} \rightarrow \text{B-Mod} \), exact = left & right exact, i.e. sends SES to SES.

3.3) **Examples:**

0) For a ring homomorphism \( \varphi : \text{A} \rightarrow \text{B} \), the pullback functor \( \varphi^* : \text{B-Mod} \rightarrow \text{A-Mod} \) is manifestly exact.

1) The localization functor \( \cdot \left[ S^{-1} \right] \) is exact: by Proposition in Section 1.2 of Lec 12, the localization functor sends kernels to kernels & images to images.

2) Let \( M \) be an \( \text{A-module} \). Then \( \text{Hom}_A (\cdot ; M) : \text{A-Mod}^{\text{opp}} \rightarrow \text{A-Mod} \) is left exact, this follows from 6) & c) of Problem 7 in HW 1.

**Exercise:** Check that \( \text{Hom}_A (M ; \cdot) : \text{A-Mod} \rightarrow \text{A-Mod} \) is left exact.

3) The tensor product functor \( M \otimes_A (\cdot) : \text{A-Mod} \rightarrow \text{A-Mod} \) is right exact, by Step 2 of the proof of Thm in Section 1.1 of Lecture 17: for a SES \( 0 \rightarrow K \rightarrow \tilde{M} \rightarrow M \rightarrow 0 \), \( M \otimes_A M \) is the quotient of \( \tilde{M} \otimes_A M \) by the image of \( K \otimes_A M \), equivalently, the sequence \( K \otimes_A M \rightarrow \tilde{M} \otimes_A M \rightarrow M \otimes_A M \rightarrow 0 \) is exact.
BONUS:

1) Additive categories.

In our definition of additive functors we need to consider categories $A$-Mod, $A$-Mod $^op$ separately. This is awkward. The concept of an "additive category" includes these examples & much more. And we can talk about additive functors between additive categories.

Definition: An additive category $C$ is

(Data) · a category
 · together w. abelian group structure on $\text{Hom}_C(X,Y)$

$\forall X,Y \in \text{Ob}(C)$

These data have to satisfy the following axioms:

· $\exists 0 \in \text{Ob}(C)$ w. $\text{Hom}_C(X,0) = \text{Hom}_C(0,X) = \{0\}$

· $\forall X,Y \in \text{Ob}(C)$, $\exists$ a product $X \times Y \in \text{Ob}(C)$

· the composition map $\text{Hom}_C(X,Y) \times \text{Hom}_C(Y,Z) \rightarrow \text{Hom}_C(X,Z)$ is bi-additive (a.k.a. $\mathbb{Z}$-bilinear), $\forall X,Y,Z \in \text{Ob}(C)$

Recall that in $\mathbb{Z}$-Mod, the product of two objects (in fact, of any finite collection) coincides w. their coproduct. This property carries over to arbitrary additive categories. The (co)product $X \times Y$ is usually called the direct sum and is denoted by $X \oplus Y$
Examples (of additive categories):

1) $A$-Mod (for a ring $A$, not necessarily commutative).
2) $A$-Mod$^{\text{op}}$
3) A full subcategory in an additive category is additive iff it's closed under taking finite direct sums. For example, in $A$-Mod we can consider the full subcategories consisting of free (or of projective) objects. They are closed under direct sums hence additive.

4*) In various parts of Geometry/Topology people consider categories of "sheaves". These categories are additive.
5*) Various constructions in Homological Algebra produce more complicated additive categories from $A$-Mod: homotopy categories of complexes, derived categories etc.

2) Abelian categories.
Additive functors make sense between additive categories, Lec 15.

Question for today: what additional structures/conditions do we need to impose in order to be able to talk about exact sequences? It turns out that no additional structures are needed but we need to impose additional conditions.

Exact sequences are about kernels, images and their coincidence. One can define them easily when we talk about modules, but in the generality of additive categories, objects are not sets & morphisms are not maps, so we need to explain what we mean by kernels.
As usual, a recipe to define the kernels (and cokernels = quotients by images) are to look at their universal properties in the usual setting of abelian groups.

Let \( N, M \) be abelian groups & \( \varphi : M \rightarrow N \) be a homomorphism.
Let \( K \) be the kernel of \( \varphi \) and \( i : K \rightarrow M \) be the inclusion. Then we have the following:

\[ (*) \quad \forall \; \ell \in \text{Ob}(\mathbb{Z}-\text{Mod}) \quad \text{&} \quad \psi : \ell \rightarrow M \quad \text{a homomorphism s.t.} \quad \varphi \circ \psi = 0 \]

\[ \exists ! \; \psi : \ell \rightarrow K \quad \text{making the following diagram commute} \]

\[
\begin{array}{ccc}
\ell & \xrightarrow{\psi} & M \\
\downarrow{\psi} & & \downarrow{\varphi} \\
K & \xrightarrow{i} & M
\end{array}
\]

Definition (of kernel in an additive category) Let \( C \) be an additive category, \( M, N \in \text{Ob}(C) \), \( \varphi \in \text{Hom}_C(M, N) \). By the kernel of \( \varphi \) we mean a pair \((K, i) \) w \( K \in \text{Ob}(C) \), \( i \in \text{Hom}_C(K, M) \) s.t.
\[ \varphi \circ i = 0 \]

\( (K, i) \) has a universal property that is a direct generalization of \((*)\).

Definition (of cokernel in an additive category) The cokernel in \( C = \text{the kernel in } C^{\text{opp}} \). I.e. in the notation of the previous definition, we get a pair \((C, j) \) w. \( C \in \text{Ob}(C) \), \( j \in \text{Hom}_C(N, C) \) s.t.
\[ j \circ \varphi = 0 \]
• and the universal property: \( \forall \psi \in \text{Hom}_C(N, L) \) s.t.
\( \psi \circ \phi = 0 \) \( \exists! \psi' \in \text{Hom}_C(C, L) \) s.t.
\[
\begin{array}{c}
N \xrightarrow{\phi} C \\
\downarrow \pi \quad \psi' \\
\end{array}
\]
is commutative.

Exercise: In the category of abelian groups, the cokernel of \( \phi: M \rightarrow N \)
is \( N/\text{im} \phi \) w. the projection \( \pi: N \rightarrow N/\text{im} \phi \).

Definition: We say that \( \phi \in \text{Hom}_C(M, N) \) is a \textbf{monomorphism} if (0, 0) is its kernel and is an \textbf{epimorphism} if (0, 0) is its cokernel.

For example, in \( A:\text{Mod} \), monomorphism = injective \& epimorphism = surjective. Note that a monomorphism in \( C = \text{epimorphism in } C^{\text{op}} \).

Exercise: • The following 2 conditions are equivalent

(2) \( \phi: M \rightarrow N \) is a monomorphism

(6) \( \phi_0 \in \text{Hom}_A(\xi, M) \rightarrow \text{Hom}_A(\xi, N) \) is inj. for \( \xi \notin \text{Ob}(C) \)

• Similarly, \( \phi_0 \) is an epimorphism \( \iff \phi_0: \text{Hom}_A(N, \xi) \rightarrow \text{Hom}_A(M, \xi) \)

• In particular, for any kernel \( (K, \xi) \) we have that \( \xi \) is a monomor-
phism \& for any cokernel \( (\xi, \eta) \), \( \eta \) is an epimorphism.

Definition: We say that an additive category \( C \) is \textit{abelian} if

(K) every morphism in \( C \) has a kernel.
(C) every morphism in C has a cokernel.
(M) for every monomorphism \( c \in \text{Hom}_C(K,M) \) \( \exists N \& y \in \text{Hom}_C(M,N) \) s.t. \( (K,c) \) is the kernel of \( y \).
(E) for every epimorphism \( \delta \in \text{Hom}_C(N,C) \) \( \exists M \& \pi \in \text{Hom}_C(M,N) \) s.t. \( (\pi,\delta) \) is the cokernel of \( y \).

Example: \( A \)-Mod \& \( A \)-Mod^{op} are abelian categories.

Non-example: The category of free \( A \)-modules is not abelian if \( A \) is not a field. This is because every (not necessarily free) \( A \)-module is the cokernel (in the usual sense) of a linear map between free modules.

Example: A full subcategory of \( A \)-Mod (where \( A \) is an associative ring) that is closed under taking sub- \& quotient modules is abelian. In particular, for \( A \) Noetherian, the category of fin. generated \( A \)-modules is abelian.

In an abelian category it makes sense to speak about subobjects of \( M \) (a pair of \( K \in \text{Ob}(C) \) \& a monomorphism \( \in \text{Hom}_C(K,M) \)) quotient objects etc. Axioms (M) \& (E) ensure that these objects behave in a way we expect them to. In particular, it does make sense to talk about exact sequences.

Premium exer: in abelian category, isomorphism \( \iff \) monomorphism \& epimorphism
